

DEFLECTION PROCESSOR

The S1D2511B01 is a monolithic integrated circuit assembled in 32 pins shrunk dual in line plastic package. This IC controls all the functions related to the horizontal and vertical deflection in multimodes or multi-frequency computer display monitors.

The internal sync processor, combined with the very powerful geometry correction block make the S1D2511B suitable for very high performance monitors with very few external components. The horizontal jitter level is very low. It is particularly well suited for high-end 15" and 17" monitors.

FUNCTIONS

- Deflection Processor
- I²C BUS Control
- B+ Regulator
- Vertical Parabola Generator
- Horizontal and Vertical dynamic focus

FEATURES

(HORIZONTAL)

- Self-adaptive
- Dual PLL concept
- 150kHz maximum frequency
- X-RAY protection input
- I²C controls : Horizontal duty-cycle, H-position, free running frequency, frequency generator for burn-in mode.

(VERTICAL)

- Vertical ramp generator
- 50 to 165Hz AGC loop
- Geometry tracking with V-POS & AMP
- I²C Controls :
V-AMP, V-POS, S-CORR, C-CORR

(I²C GEOMETRY CORRECTIONS)

- Vertical parabola generator
(Pincushion-E/W, Keystone)

ORDERING INFORMATION

Device	Package	Operating Temperature
S1D2511B01-A0B0	32-SDIP	0 °C — 70°C

- Horizontal Dynamic Phase
(Side Pin balance & parallelogram)
- Horizontal and vertical dynamic focus
(Horizontal Focus Amplitude, Horizontal Focus Symmetry, Vertical Focus Amplitude)

(GENERAL)

- Sync Processor
- 12V supply voltage
- Hor. & Vert, lock/unlock outputs
- Read/Write I²C interface
- Vertical moire
- B+ Regulator
 - Internal PWM generator for B+ current mode step-up converter.
 - Switchable to step-down converter
 - I²C adjustable B+ reference voltage
 - Output pulses synchronized on horizontal frequency
 - Internal maximum current limitation.

BLOCK DIAGRAM

PIN CONFIGURATIONS

PIN DESCRIPTION

Table 1. Pin Description

No	Pin Name	Description
1	H/HVIN	TTL compatible horizontal sync input(Separate or composite)
2	VSYNCIN	TTL compatible vertical sync input (for separated H&V)
3	HLOCKOUT	First PLL lock/unlock output (0V unlocked - 5V locked)
4	PLL2C	Second PLL loop filter
5	C0	Horizontal oscillator capacitor
6	R0	Horizontal oscillator resistor
7	PLL1F	First PLL loop filter
8	HPOSITION	Horizontal position filter(Capacitor to be connected to HGND)
9	HFOCUSCAP	Horizontal dynamic focus oscillator capacitor
10	FOCUSOUT	Mixed horizontal and vertical dynamic focus output
11	HGND	Horizontal Section Ground
12	HFLY	Horizontal Flyback Input (positive polarity)
13	HREF	Horizontal Section Reference Voltage (to be filtered)
14	COMP	B+ error amplifier output for frequency compensation and gain setting
15	REGIN	Regulation input of B+ control loop
16	ISENSE	Sensing of external B+ switching transistor current or switch for step-down converter
17	B+GND	Ground (related to B+ reference adjustment)
18	BREATH	DC breathing input control(Compensation of vertical amplitude against EHV variation)
19	VGND	Vertical section ground
20	VAGCCAP	Memory capacitor for automatic gain control loop in vertical ramp generator
21	VREF	Vertical section reference voltage (to be filtered)
22	VCAP	Vertical sawtooth generator capacitor
23	VOUT	Vertical ramp output (with frequency independant amplitude and S or C corrections if any). It is mixed with vertical position voltage and vertical moire.
24	EWOUT	Pincushion-East/West correction parabola output
25	XRAY	X-RAY protection input (with internal latch function)
26	HOUT	Horizontal drive output (internal transistor, open collector)
27	GND	General ground (referenced to Vcc)
28	BOUT	B+ PWM regulator output
29	Vcc	Supply voltage (12V typ)
30	SCL	I ² C clock input
31	SDA	I ² C data input
32	5V	Supply voltage (5V typ)

REFERENCE DATA

Table 2. Reference Data

Parameter	Value	Unit
Horizontal frequency	15 to 150	kHz
Autosynch frequency (for given R0 and C0)	1 to 4.5FO	FH
± Horizontal sync polarity input	YES	
Polarity detection (on both horizontal and vertical section)	YES	
TTL Composite synch	YES	
Lock/Unlock identification (on both horizontal 1st PLL and vertical section)	YES	
I ² C control for H-Position	±10	%
XRay protection	YES	
I ² C horizontal duty cycle adjust	30 to 60	%
I ² C free running frequency adjustment	0.8 to 1.3FO	FH
Stand-by function	YES	
Dual polarity H-Drive outputs	NO	
Supply voltage monitoring	YES	
PLL1 inhibition possibility	NO	
Blanking output	NO	
Vertical frequency	35 to 200	Hz
Vertical autosync (for 150nF on Pin22 and 470nF on Pin20)	50 to 165	Hz
Vertical S-Correction	YES	
Vertical C-Correction	YES	
Vertical amplitude adjustment	YES	
DC breathing control on Vertical amplitude	YES	
East/West parabola output(also known as Pin cushion output)	YES	
East/West correction amplitude adjustment	YES	
Keystone adjustment	YES	
Internal dynamic horizontal phase control	YES	
Side pin balance amplitude adjustment	YES	
Parallelogram adjustment	YES	
Tracking of geometric corrections with vertical amplitude and position	YES	

Table 2. Reference Data (Continued)

Parameter	Value	Unit
Reference voltage (both on horizontal and vertical)	YES	
Dynamic focus (both on horizontal and vertical)	YES	
I ² C horizontal dynamic focus amplitude adjustment	YES	
I ² C horizontal dynamic focus symmetry adjustment	YES	
I ² C vertical dynamic focus amplitude adjustment	YES	
Deflection of input Sync type(biased from 5V alone)	YES	
Vertical moire output	YES	
I ² C controlled V-moire amplitude	YES	
Frequency generator for burn-in	YES	
Fast I ² C read/write	400	kHz
B+ regulation adjustable by I ² C	YES	

ABSOLUTE MAXIMUM RATINGS

No	Item	Symbol	Value	Unit

NOTES;

1. Duty cycle is the ratio of power transistor OFF time period. Power transistor is OFF when output transistor is OFF.
2. Initial condition for safe operation start up.
3. S and C correction are inhibited so the output sawtooth has a linear shape.
4. With register 07 at byte x0xxxxxx (s-correction control is inhibited) then the S correction is inhibited, consequently the sawtooth has a linear shape.
5. With register 08 at byte x0xxxxxx (C-Correction control is inhibited) then the C correction is inhibited, consequently the sawtooth has a linear shape.
6. It is frequency range for which the vertical oscillator will automatically synchronize, using a single capacitor value on pin 22, and with a constant ramp amplitude.
7. These parameters are not tested on each unit. They are measured during out internal qualification.
8. Refers to notes 4 & 5 from last section.
9. TH is the Horizontal period.
10. These parameters are not tested on each unit. They are measured during our internal qualification procedure which includes characterization on batches coming from corners of our processes and also temperature characterization.
11. See Figure 11 for explanation of reference phase.
12. See Figure 15.
13. This is the frequency range for which the vertical oscillator will automatically synchronize, using a single capacitor value on Pin 22 and with a constant ramp amplitude.
14. TV is the vertical period.
15. When not used the DC breathing control pin must be connected to 12V.
16. The external power transistor is OFF during 400ns of the HFOCUSCAP discharge.

OPERATING DESCRIPTION

GENERAL CONSIDERATIONS

Power Supply

The typical values of the power supply voltages V_{CC} and V_{DD} are respectively 12V and 5V. Perfect operation is obtained if V_{CC} and V_{DD} are maintained in the limits: 10.8 to 13.2V and 4.5 to 5.5V.

In order to avoid erratic operation of the circuit during transient phase of V_{CC} switching on, or switching off, the value of V_{CC} is monitored and the outputs of the circuit are inhibited if V_{CC} is less than 7.5V typically.

In the same manner, V_{DD} is monitored and internal set-up is made until V_{DD} reaches 4V (see I²C control table for power on reset).

In order to have a very good power supply rejection, the circuit is internally powered by several internal voltage references (the unique typical value of which is 8V). Two of these voltage references are externally accessible, one for the vertical part and one for the horizontal one. If needed, these voltage references can be used (until I_{load} is less than 5mA). Furthermore it is necessary to filter the a.m. voltage references by the use of external capacitor connected to ground, in order to minimize the noise and consequently the "jitter" on vertical and horizontal output signals.

I²C Control

KB2511 belongs to the I²C controlled device family, instead of being controlled by DC voltage on dedicated control pins, each adjustment can be realized through the I²C interface. The I²C bus is a serial bus with a clock and a data input. The general function and the bus protocol are specified in the Philips-bus data sheets.

The interface (data and clock) is TTL-level compatible. The internal threshold level of the input comparator is 2.2V (when V_{DD} is 5V). Spikes of up to 500ns are filtered by an integrator and maximum clock speed is limited to 400kHz.

The data line (SDA) can be used in a bidirectional way that means in read-mode the IC clocks out a reply information (1byte) to the micro-processor.

The bus protocol prescribes always a full-byte transmission. The first byte after the start condition is used to transmit the IC-address (hexa 8C for write, 8D for read).

Write Mode

In write mode the second byte sent contains the subaddress of the selected function to adjust (or controls to affect) and the third byte the corresponding data byte. It is possible to send more than one data byte to the IC. If after the third byte no stop or start condition is detected, the circuit increments automatically the momentary subaddress in the subaddress counter by one (auto-increment mode). So it is possible to transmit immediately the next data bytes without sending the IC address or subaddress. It can be useful so as to reinitialize the whole controls very quickly (flash manner). This procedure can be finished by a stop condition.

The circuit has 16 adjustment capabilities: 3 for horizontal part, 4 for vertical one, 2 for E/W correction, 2 for the dynamic horizontal phase control, 1 for moire option, 3 for horizontal and vertical dynamic focus and 1 for B+ reference adjustment.

17 bits are also dedicated to several controls (ON/OFF, horizontal forced frequency, sync priority, detection refresh and Xray reset).

Read Mode

During read mode the second byte transmits the reply information.

The reply byte contains horizontal and vertical lock/unlock status, Xray activated or not, the horizontal and vertical polarity detection. It also contains synchro detection status that is useful for μ P to assign sync priority.

A stop condition always stops all activities of the bus decoder and switches the data and the clock line (SDA and SCL) to high impedance.

See I²C subaddress and control tables.

Sync processor

The internal sync processor allows the S1D2511B01 to accept any kind of input synchro signals:

- separated horizontal & vertical TTL-compatible sync signals,
- composite horizontal & vertical TTL-compatible sync signals.

Sync identification Status

The MCU can read (address read mode : 8D) the status register via the I²C bus, and then select the sync priority depending on this status.

Among other data this register indicates the presence of sync pulses on H/HVIN, VSYNCIN and (when 12V is supplied) whether a Vext has been extracted from H/HVIN. Both horizontal and vertical sync are detected even if only 5V is supplied.

In order to choose the right sync priority the MCU may proceed as follows (see I²C Address Table):

- refresh the status register,
- wait at least for 20ms (MAX. vertical period),
- read this status register,

Sync priority choice should be:

Vext det	H/V det	V det	Sync priority subaddress 03 (D8)	Comment sync type
No	Yes	Yes	1	Separated H & V
Yes	Yes	No	0	Composite TTL H & V

Of course, when choice is made, one can refresh the sync detections and verify that extracted Vsync is present and that no sync change occurred.

Sync processor is also giving sync polarity information.

IC status

The IC can inform the MCU about the 1st horizontal PLL and vertical section status, and about the Xray protection (activated or not). Resetting the XRAY internal latch can be done either by decreasing the Vcc supply or directly resetting it via the I²C interface.

Sync Inputs

Both H/HVin and Vsyncin inputs are TTL compatible trigger with hysteresis to avoid erratic detection.

Both inputs include a pull up register connected to V_{DD}.

Sync Processor Output

The sync processor indicates on the HLOCKOUT Pin whether 1st PLL is locked to an incoming horizontal sync. HLOCKOUT is a TTL compatible CMOS output. Its level goes to high when locked. In the same time the D8 bit of the status register is set to 0. This information is mainly used to trigger safety procedures (like reducing B+ value) as soon as a change is detected on the incoming sync. Further to this, it may be used in an automatic procedure for

free running frequency(f_0) adjustment.

Sending the desired f_0 on the sync input and progressively decreasing the free running frequently I^2C register value(address 02), the HLOCKOUT Pin will go high as soon as the proper setting is reached. Setting the free running frequency this way allows to fully exploit the S1D2511B01 horizontal frequency range.

HORIZONTAL PART

Internal input conditions

Horizontal part is internally fed by synchro processor with a digital signal corresponding to horizontal synchro pulses or to TTL composite input.

concerning the duty cycle of the input signal, the following signals (positive or negative) may be applied to the circuit.

Using internal integration, both signals are recognized on condition that $Z/T < 25\%$, synchronisation occurs on the leading edge of the internal sync signal. The minimum value of Z is $0.7\mu s$.

Figure 6.

An other integration is able to extract vertical pulse of composite synchro if duty cycle is more than 25% (typically $d = 35\%$) ⁽⁷⁾

Figure 7.

The last feature performed is the equalizing pulses removing to avoid parasitic pulse on phase comparator input which is intolerant to wrong or missing pulse.

PLL1

The PLL1 is composed of a phase comparator, an external filter and a voltage control oscillator (VCO).

The phase comparator is a phase frequency type designed in CMOS technology. This kind of phase detector avoids locking on false frequencies. It is followed by a charge pump, composed of two current sources sunk and sourced ($I = 1mA$ typ. when locked, $I = 140mA$ when unlocked). This difference between lock/unlock permits a smooth catching of horizontal frequency by PLL1. This effect is reinforced by an internal original slow down system when PLL1 is locked avoiding horizontal too fast frequency change.

The dynamic behaviour of the PLL is fixed by an external filter which integrates the current of the charge pump.

A CRC filter is generally used (see figure 8)

**Figure 8.**

PLL1 is internally inhibited during extracted vertical sync (if any) to avoid taking in account missing pulses or wrong pulse on phase comparator. The inhibition results from the opening of a switch located between the charge pump and the filter (see figure 9).

The VCO uses an external RC network. It delivers a linear sawtooth obtained by charge and discharge of the capacitor, by a current proportionnal to the current in the resistor. Typical thresholds of sawtooth are 1.6V and 6.4V.

**Figure 9. Block Diagram**

Figure 10. Details of VCO

The control voltage of the VCO is typically comprised between 1.33V and 6V (see figure 10). The theoretical frequency range of this VCO is in the ratio 1 to 4.5, the effective frequency range has to be smaller 1 to 4.2 due to clamp intervention on filter lowest value. To avoid spread of external components and the circuit itself, it is possible to adjust free running frequency through I^2C . This adjustment can be made automatically on the manufacturing line without manual operation by using hlock/unlock information. The adjustment range is 0.8 to 1.3 F_0 (where 1.3 F_0 is the free running frequency at power on reset).

The sync frequency has to be always higher than the free running frequency. As an example for a synchro range from 24kHz to 100kHz, the suggested free running frequency is 23kHz.

An other feature is the capability for MCU to force horizontal frequency throw I^2C to $2 \times F_0$ or $3 \times F_0$ (for burn in mode or safety requirement). In this case, inhibition switch is opened leaving PLL1 free but voltage on PLL1 filter is forced to 2.66V for $2 \times F_0$ or 4.0V for $3 \times F_0$.

The PLL1 ensures the coincidence between the leading edge of the synchro signal and a phase reference obtained by comparison between the sawtooth of the VCO and an internal DC voltage I^2C adjustable between 2.65V and 3.75V (corresponding to $\pm 10\%$) (see figure 11)

Phase REF1 is obtained by comparison between the sawtooth and a DC voltage adjustable between 2.6V and 3.8V. The PLL1 ensures the exact coincidence between the signals phase REF and HSYNS. A $\pm T_H/10$ phase adjustment is possible

Figure 11. PLL1 Timing Diagram

The S1D2511B01 also includes a lock/unlock identification block which senses in real time whether PLL1 is locked or not on the incoming horizontal sync signal. The resulting information is available on Hlockout (see sync processor). The block function is described in figure 12.

When PLL1 is unlocked, It forces Hlockout to leave high.

The lock/unlock information is also available throw I²C read.

PLL2

The PLL2 ensures a constant position of the shaped flyback signal in comparism with the sawtooth of the VCO (figure 12).

The phase comparator of PLL2 (phase type comparator) is followed by a charge pump(typical output current:0.5mA).

The flyback input is composed of an NPN transistor. This input must be current driven. The maximum recomanded input current is 5mA (see figure 13).

The dury cycle is adjustable through I²C from 30% to 60%. For startup safe operation, initial duty cycle (after power on reset) is 60% in order to avoid having a too long conduction period of the horizontal scanning transistor. The maximum storage time($T_{s\text{ MAX.}}$) is $(0.38T_H - T_{FLY}/2)$. Typically, T_{FLY}/T_H is around 20% which means that $T_{s\text{ max}}$ is around 28% of T_H .

Figure 12. PLL2 Timing Diagram

Figure 13. Flyback Input Electrical Diagram

Output Section

The H-drive signal is transmitted to the output through a shaping block ensuring TS and I^2C adjustable duty cycle. In order to secure scanning power part operation, the output is inhibited in the following circumstances:

- Vcc too low
- Xray protection activated
- During horizontal flyback
- H Drive I^2C bit control is off.

The output stage is composed of a NPN bipolar transistor. Only the collector is accessible (see figure 14).

Figure 14.

The output NPN is in off-state when the power scanning transistor is also in off-state.

The maximum output current is 30mA, and the corresponding voltage drop of the output V_{CEsat} is 0.4V typically. It is evident that the power scanning transistor cannot be directly driven by the integrated circuit. An interface has to be designed between the circuit and the power transistor which can be of bipolar or MOS type.

X-RAY protection

The activation of the X-ray protection is obtained by application of a high level on the X-ray input (8V on pin 25). It inhibits the H-Drive and B+ outputs.

This protection is latched; It may be reset either by Vcc switch off or by I^2C (see figure 15).

Horizontal and vertical dynamic focus

The S1D2511B01 delivers and horizontal parabola added on a vertical parabola waveform on pin 10. This horizontal parabola is performed from a sawtooth in phase with flyback pulse middle. This sawtooth is present on pin 9 where the horizontal focus capacitor is the same as C0 to obtain a controlled amplitude (from 2 to 4.7V typically). Symmetry (keystone) and amplitude are I^2C adjustable (see figure 16). Vertical dynamic focus is tracked with VPOS and VAMP. Its amplitude can be adjusted. It is also affected by S and C corrections. This positive signal has to be connected to the CRT focusing grids.

Figure 15. Safety Functions Block Diagram

Figure 16.

VERTICAL PART

Geometric Corrections

The principle is represented in figure 17.

Figure 17. Geometric Corrections Principle

Starting from the vertical ramp, a parabola shaped current is generated for E/W correction, dynamic horizontal phase control correction, and vertical dynamic focus correction.

The base of the parabola generator is an analog multiplier, the output current of which is equal to:

$$\Delta I = k \cdot (V_{OUT} - V_{DCMID})^2$$

Where V_{out} is the vertical output ramp (typically between 2 and 5V) and V_{DCMID} is 3.5V (for $V_{REF-V}=8V$). The V_{OUT} sawtooth is typically centered on 3.5V. By changing the vertical position, the sawtooth shifts by $\pm 0.3V$.

In order to keep a good screen geometry for any end user preference adjustment we implemented the geometry tracking.

Due to large output stages voltage range (E/W, FOCUS), the combination of tracking function with maximum vertical amplitude max or min vertical position and maximum gain on the DAC control may lead to the output stages saturation. This must be avoided by limiting the output voltage by appropriate I²C registers values.

For E/W part and Dynamic Horizontal phase control part, a sawtooth shaped differential current in the following form is generated:

$$\Delta I' = k' \cdot (V_{OUT} - V_{DCMID})^2$$

Then ΔI and $\Delta I'$ are added together and converted into voltage for the E/W part.

Each of the two E/W components or the two Dynamic horizontal phase control ones may be inhibited by their own I²C select bit.

The E/W parabola is available on pin 24 by the way of an emitter follower which has to be biased by an external resistor (10K Ω). It can be DC coupled with external circuitry.

Vertical dynamic focus is combined with horizontal one on output pin 10. Dynamic horizontal phase control current drives internally the H-position, moving the Hfly position on the horizontal sawtooth in the $\pm 1.4\%$ Th both on side pin balance and parallelogram.

EW

$$EW_{OUT} = 2.5V + K1 (V_{OUT} - V_{DCMID})^2 + K2 (V_{OUT} - V_{DCMID})$$

K1 is adjustable by EW amplitude I²C register

K2 is adjustable by keystone I²C register

Dynamic horizontal phase control

$$I_{OUT} = K3 (V_{OUT} - V_{DCMID})^2 + K4 (V_{OUT} - V_{DCMID})$$

K4 is adjustable by side pin balance I²C register

K3 is adjustable by parallelogram I²C register.

Function

When the synchronisation pulse is not present, an internal current source sets the free running frequency. For an external capacitor, $C_{OSC} = 150nF$, the typical free running frequency is 100Hz.

Typical free running frequency can be calculated by:

$$f_0 \text{ (Hz)} = 1.5 \cdot 10^{-5} \cdot \frac{1}{C_{OSC}}$$

A negative or positive TTL level pulse applied on pin 2 (VSYNC) as well as a TTL composite sync on pin 1 can synchronise the ramp in the range $[f_{min}, f_{max}]$. This frequency range depends on the external capacitor connected on pin 22. A capacitor in the range $[150nF, 220nF] \pm 5\%$ is recommended for application in the following range: 50Hz to 165Hz.

Typical maximum and minimum frequency, at 25°C and without any correction (S correction or C correction), can be calculated by:

$$f_{(Max.)} = 2.5 \times f_0 \text{ and } f_{(Min.)} = 0.33 \times f_0$$

If S or C corrections are applied, these values are slightly affected.

If a synchronisation pulse is applied, the internal oscillator is automatically caught but the amplitude is no more constant. An internal correction is activated to adjust it in less than a half a second : the highest voltage of the ramp pin 22 is sampled on the sampling capacitor connected on pin 20 at each clock pulse and a transconductance amplifier generates the charge current of the capacitor. The ramp amplitude becomes again constant.

The read status register enables to have the vertical lock-unlock and the vertical sync polarity informations.

It is recommended to use a AGC capacitor with low leakage current. A value lower than 100nA is mandatory.

Good stability of the internal closed loop is reached by a $470nF \pm 5\%$ capacitor value on pin 20 (VAGC)

Figure 18. AGC Loop Block Diagram

I²C Control Adjustments

Then, S and C correction shapes can be added to this ramp. This frequency independent S and C corrections are generated internally. Their amplitude are adjustable by their respective I²C register. They can also be inhibited by their select bit. Endly, the amplitude of this S and C corrected ramp can be adjusted by the vertical ramp amplitude control register. The adjusted ramp is available on pin 23 (VOUT) to drive an external power stage. The gain of this stage is typically 25% depending on its register value. The mean value of this ramp is driven by its own I²C register (vertical position). Its value is $V_{POS} = 7/16 \cdot V_{REF} \pm 300\text{mV}$.

Usually VOUT is sent through a resistive divider to the inverting input of the booster. Since VPOS derives from V_{REF-V} , the bias voltage sent to the non-inverting input of booster should also derive from V_{REF-V} to optimize the accuracy(see Application Diagram).

Basic Equations

In first approximation, the amplitude of the ramp on pin 23 (Vout) is:

$$V_{OUT} - V_{POS} = (V_{OSC} - V_{DCMID}) \cdot (1 + 0.25 (V_{AMP}))$$

with:

- $V_{DCMID} = 7/16 \cdot V_{REF}$ (typically 3.5V, the middle value of the ramp on pin 22)
- $V_{OSC} = V_{22}$ (ramp with fixed amplitude)
- $V_{AMP} = -1$ for minimum vertical amplitude register value and $+1$ for maximum
- V_{POS} is calculated by : $V_{POS} = V_{DCMID} + 0.3V_p$ with V_p equals -1 for minimum vertical position register value and $+1$ for maximum

The current available on Pin 22 is :

$$I_{OSC} = \frac{3}{8} \cdot V_{REF} \cdot C_{OSC} \cdot f$$

with C_{OSC} : capacitor connected on pin 22
 f : synchronisation frequency.

Vertical Moire

By using the vertical moire, VPOS can be modulated from to frame. This function is intended to cancel the fringes which appear when line to line interval is very close to the CRT vertical pitch. The amplitude of the modulation is controlled by register VMOIRE on sub-off via the control bit D7.

DC/DC CONVERTER PART

This unit controls the switch-mode DC/DC converter. It converts a DC constant voltage into the B+ voltage (roughly proportional to the horizontal frequency) necessary for the horizontal scanning. This DC/DC converter can be configured either in step-up or step-down mode. In both cases it operates very similarly to the well known UC3842.

Step-up Mode

Operating Description

- The power MOS is switched-on during the flyback (at the beginning of the positive slope of the horizontal focus sawtooth).
- The power MOS is switched-off when its current reaches a predetermined value. For this purpose, a sense resistor is inserted in its source. The voltage on this resistor is sent to Pin16 (I_{SENSE}).
- The feedback (coming either from the EHV or from the flyback) is divided to a voltage close to 4.8V and compared to the internal 4.8V reference (V_{REF}). The difference is amplified by an error amplifier, the output of which controls the power MOS switch-off current.

Main Features

- Switching synchronized on the horizontal frequency,
- B+ voltage always higher than the DC source, - Current limited on a pulse-by-pulse basis.

Step-down Mode

In step-down mode, the I_{sense} information is not used any more and therefore not sent to the Pin16. This mode is selected by connecting this Pin16 to a DC voltage higher than 6V (for example V_{REF-V}).

Operating Description

- The power MOS is switched-on as for the step-up mode.
- The feedback to the error amplifier is done as for the step-up mode.
- The power MOS is switched-off when the HFOCUSCAP voltage gets higher than the error amplifier output voltage.

Main Features

- Switching synchronized on the horizontal frequency,
- B+ voltage always lower than the DC source,
- No current limitation.

APPLICATION CIRCUIT
