

1.5 μ A IQ, Step-Up DC-DC Converters in Thin SOT23-5

General Description

The MAX1722/MAX1723/MAX1724 compact, high-efficiency, step-up DC-DC converters are available in tiny, 5-pin thin SOT23 packages. They feature an extremely low 1.5 μ A quiescent supply current to ensure the highest possible light-load efficiency. Optimized for operation from one to two alkaline or nickel-metal-hydride (NiMH) cells, or a single Li+ cell, these devices are ideal for applications where extremely low quiescent current and ultra-small size are critical.

Built-in synchronous rectification significantly improves efficiency and reduces size and cost by eliminating the need for an external Schottky diode. All three devices feature a 0.5 Ω N-channel power switch. The MAX1722/MAX1724 also feature proprietary noise-reduction circuitry, which suppresses electromagnetic interference (EMI) caused by the inductor in many step-up applications. The family offers different combinations of fixed or adjustable outputs, shutdown, and EMI reduction (see *Selector Guide*).

Figure 1. MAX1723 Simplified Functional Diagram

Detailed Description

The MAX1722/MAX1723/MAX1724 compact, high-efficiency, step-up DC-DC converters are guaranteed to start up with voltages as low as 0.91V and operate with an input voltage down to 0.8V. Consuming only 1.5 μ A of quiescent current, these devices include a built-in synchronous rectifier that reduces cost by eliminating the need for an external diode and improves overall efficiency by minimizing losses in the circuit (see *Synchronous Rectification* section). The MAX1722/MAX1724 feature a clamp circuit that reduces EMI due to inductor ringing. The MAX1723/MAX1724 feature an active-low shutdown that reduces quiescent supply current to 0.1 μ A. The MAX1722/MAX1723 have an adjustable output voltage, while the MAX1724 is available with four fixed-output voltage options (see *Selector Guide*). Figure 1 is the MAX1723 simplified functional diagram and Figure 2 is the MAX1724 simplified functional diagram.

PFM Control Scheme

A forced discontinuous, current-limited, pulse-frequency-modulation (PFM) control scheme is a key feature of the

MAX1722/MAX1723/MAX1724. This scheme provides ultra-low quiescent current and high efficiency over a wide output current range. There is no oscillator; the inductor current is limited by the 0.5A N-channel current limit or by the 5 μ s switch maximum on-time. Following each on cycle, the inductor current must ramp to zero before another cycle may start. When the error comparator senses that the output has fallen below the regulation threshold, another cycle begins.

Synchronous Rectification

The internal synchronous rectifier eliminates the need for an external Schottky diode, thus reducing cost and board space. While the inductor discharges, the P-channel MOSFET turns on and shunts the MOSFET body diode. As a result, the rectifier voltage drop is significantly reduced, improving efficiency without the addition of external components.

Low-Voltage Startup Circuit

The MAX1722/MAX1723/MAX1724 contain a low-voltage startup circuit to control DC-DC operation until the output voltage exceeds 1.5V (typ). The minimum start-

MAX1722/MAX1723/MAX1724

lacks a BATT pin; therefore, this circuit is powered through the OUT pin. Adding a Schottky diode in parallel with the P-channel synchronous rectifier allows for startup voltages as low as 1.2V for the MAX1723 (Figure 3). The external Schottky diode is not needed for input voltages greater than 1.8V. Once started, the output maintains the load as the battery voltage decreases below the startup voltage.

The MAX1723/MAX1724 enter shutdown when the $\overline{\text{SHDN}}$ pin is driven low. During shutdown, the body diode of the P-channel MOSFET allows current to flow from the battery to the output. V_{OUT} falls to approximately $V_{\text{IN}} - 0.6\text{V}$ and LX remains high impedance. Shutdown can be pulled as high as 6V, regardless of the voltage at BATT or OUT. For normal operation, connect $\overline{\text{SHDN}}$ to the input.

Figure 5. LX Ringing Without Damping Switch (MAX1723)

Figure 6. LX Ringing With Damping Switch (MAX1722/MAX1724)

BATT/Damping Switch (MAX1722/MAX1724)

The MAX1722/MAX1724 include an internal damping switch (Figure 4) to minimize ringing at LX and reduce EMI. When the energy in the inductor is insufficient to supply current to the output, the capacitance and inductance at LX form a resonant circuit that causes ringing. The damping switch supplies a path to quickly dissipate this energy, suppressing the ringing at LX. This does not reduce the output ripple, but does reduce EMI with minimal impact on efficiency. Figures 5 and 6 show the LX node voltage waveform without and with the damping switch, respectively.

Design Procedure

Setting the Output Voltage (MAX1722/MAX1723)

The output voltage can be adjusted from 2V to 5.5V using external resistors R1 and R2 (Figure 7). Since FB leakage is 20nA (max), select feedback resistor R1 in the 100kΩ to 1MΩ range. Calculate R2 as follows:

$$R2 = R1 \left(\frac{V_{OUT}}{V_{FB}} - 1 \right)$$

where $V_{FB} = 1.235V$.

Figure 7. Adjustable Output Circuit

Inductor Selection

The control scheme of the MAX1722/MAX1723/MAX1724 permits flexibility in choosing an inductor. A 10µH inductor value performs well in most applications. Smaller inductance values typically offer smaller physical size for a given series resistance, allowing the smallest overall circuit dimensions. Circuits using larger inductance values may start up at lower battery voltages, provide higher efficiency, and exhibit less ripple, but they may reduce the maximum output current. This occurs when the inductance is sufficiently large to prevent the maximum current limit (I_{LIM}) from being reached before the maximum on-time ($t_{ON(MAX)}$) expires.

For maximum output current, choose the inductor value so that the controller reaches the current-limit before the maximum on-time is triggered:

$$L < \frac{V_{BATT} t_{ON(MAX)}}{I_{LIM}}$$

where the maximum on-time is typically 5µs, and the current limit (I_{LIM}) is typically 500mA (see *Electrical Characteristics* table).

For larger inductor values, determine the peak inductor current (I_{PEAK}) by:

$$I_{PEAK} = \frac{V_{BATT} t_{ON(MAX)}}{L}$$

Figure 8. MAX1724 Standard Application Circuit

The inductor's incremental saturation current rating should be greater than the peak switching current. However, it is generally acceptable to bias the inductor into saturation by as much as 20%, although this will slightly reduce efficiency. Table 1 lists suggested inductors and suppliers.

Maximum Output Current

The maximum output current depends on the peak inductor current, the input voltage, the output voltage, and the overall efficiency (η):

$$I_{OUT(MAX)} = \frac{1}{2} I_{PEAK} \left(\frac{V_{BATT}}{V_{OUT}} \right) \eta$$

For most applications, the peak inductor current equals the current limit. However, for applications using large inductor values or low input voltages, the maximum on-time limits the peak inductor current (see *Inductor Selection* section).

Capacitor Selection

Choose input and output capacitors to supply the input and output peak currents with acceptable voltage ripple. The input filter capacitor (C_{IN}) reduces peak currents drawn from the battery and improves efficiency. Low equivalent series resistance (ESR) capacitors are recommended. Ceramic capacitors have the lowest ESR, but low ESR tantalum or polymer capacitors offer a good balance between cost and performance.

Output voltage ripple has two components: variations in the charge stored in the output capacitor with each LX pulse, and the voltage drop across the capacitor's ESR caused by the current into and out of the capacitor:

$$V_{\text{RIPPLE}} = V_{\text{RIPPLE(C)}} + V_{\text{RIPPLE(ESR)}}$$

$$V_{\text{RIPPLE(ESR)}} \approx I_{\text{PEAK}} R_{\text{ESR(COUT)}}$$

$$V_{\text{RIPPLE(C)}} \approx \frac{1}{2} \left(\frac{L}{(V_{\text{OUT}} - V_{\text{BATT}}) C_{\text{OUT}}} \right) (I_{\text{PEAK}}^2 - I_{\text{OUT}}^2)$$

where I_{PEAK} is the peak inductor current (see *Inductor Selection* section). For ceramic capacitors, the output voltage ripple is typically dominated by V_{RIPPLE(C)}. For example, a 10μF ceramic capacitor and a 10μH inductor typically provide 75mV of output ripple when stepping up from 3.3V to 5V at 50mA. Low input-to-output voltage differences (i.e. two cells to 3.3V) require higher output capacitor values.

Capacitance and ESR variation of temperature should be considered for best performance in applications with wide operating temperature ranges. Table 2 lists suggested capacitors and suppliers.

PC Board Layout Considerations

Careful PC board layout is important for minimizing ground bounce and noise. Keep the IC's GND pin and the ground leads of the input and output capacitors less than 0.2in (5mm) apart using a ground plane. In addition, keep all connections to FB (MAX1722/MAX1723 only) and LX as short as possible.
