330MHz Buffered Video Switches/ Crosspoint Building Blocks

General Description

The MAX4111/MAX4121/MAX4221 wideband video switches are optimized for high-definition, broadcast-quality, composite (HDTV, NTSC, PAL, SECAM, and RGB) video switching arrays. Their open-loop buffer amplifiers offer 0.1dB gain flatness to 150MHz. They operate from $\pm 5V$ supplies and feature differential phase and gain error of only 0.01°/0.01%, respectively. The ultra-low switching glitch (13mV) is positive to avoid confusion with any sync pulse.

Ideal as building blocks in large arrays, these devices feature a constant, high input impedance and a disable function that puts the outputs into a high-impedance state and reduces the operating current to only 250 μ A. The open-loop architecture allows the outputs to drive capacitive loads without oscillation. Other key features include -92dB crosstalk and -78dB isolation (MAX4121).

The MAX4111/MAX4121/MAX4221 are offered in narrow plastic DIP and SO packages. See the table below for key features:

PART	DESCRIPTION	PINS
MAX4111	SPST, single-input, single-output switch	8
MAX4121	SPDT, 2-input, single-output switch	8
MAX4221	Dual, SPDT, 2-input, single-output switch	16

Applications

Video-Router and Crosspoint Arrays
Broadcast/HDTV-Quality Color Signal Multiplexing
RF and IF Routing
Graphics Color-Signal Routing
Telecom Routing
Data Acquisition

Features

- ♦ -3dB Bandwidth of 330MHz
- ♦ 0.1dB Gain Flatness of 150MHz
- ♦ 700V/ μ s Slew Rate
- ♦ 0.01°/0.01% Differential Phase/Gain
- ♦ Low Power: 5.5mA Max
- ♦ -92dB Crosstalk and -78dB Off Isolation at 30MHz
- ♦ High-Z Outputs when Disabled
- ♦ 3pF Input Capacitance
- ♦ Ultra-Low Switching Glitch
- ♦ On-Board Control Logic

MAX4111/MAX4121/MAX4221

Detailed Description

The MAX4111/MAX4121/MAX4221 video switches are manufactured with Maxim's proprietary, ultra-high frequency, complementary bipolar process that yields high bandwidth and low capacitance. Make-before-break switching is used to reduce noise and glitches, even when switching from part to part in large arrays. The input buffers provide a constant high input impedance, and prevent the make-before-break action from feeding back to the input.

The design of the switching mechanism limits the inevitable glitch to less than 13mVp-p. In addition, the glitch pulse is positive to avoid confusion with negative sync pulses.

Unity-gain buffers isolate other inputs from the switching action of large multiplex arrays. These buffers can drive 5k Ω resistive loads. In addition, these devices drive capacitive loads without oscillation. Load capacitance is limited only by system bandwidth requirements.

The MAX4111/MAX4121/MAX4221 do not contain buffer latches. The digital inputs are transparent.

Applications Information

Grounding, Bypassing, and PC Board Layout

To obtain the full 330MHz bandwidth of these switches, Microstrip and Stripline techniques are recommended. To ensure your PC board does not degrade the switch's performance, it's wise to design the board for a frequency greater than 1GHz. Even with very short runs, it's good practice to use this technique at critical points such as inputs and outputs.

Use the following guidelines when designing the board:

- Do not use wire-wrap boards, because they are too inductive.
- Do not use IC sockets. They increase parasitic capacitance and inductance.

- In general, surface-mount components have shorter leads and lower parasitic reactance, and give better high-frequency performance than through-hole components.
- The PC board should have at least two layers, with one side a signal side and the other a ground plane.
- Keep signal lines as short and straight as possible. Do not make 90° turns; round all corners.
- The ground plane should be as free from voids as possible.

Bypass Components—Capacitors

Surface-mount ceramic capacitors are recommended to achieve good high-frequency bypassing. A 0.1μF capacitor in parallel with a 1000pF capacitor should be used for each supply. The capacitors should be located as close to the ICs supply pins as possible, with the smaller value capacitor being closer to the IC than the other.

Creating Larger Arrays

The MAX4111/MAX4121/MAX4221 were designed as building blocks for larger arrays. The single-pole switch allows the system designer much greater control over crosstalk than multiple switches in a single IC. For this reason, cable drivers have not been included in the switch design because of the high-power drive required (see Figure 6).

Even though the stability of these devices is not worsened by adding capacitance, you may want to limit the number of switches connected together. The MAX4111/MAX4121/MAX4221 have a finite input capacitance of about 3pF and a dynamic output resistance of about 20Ω. This causes a pole at a little more than 2.7GHz. However, in a large array with many switch inputs, the total capacitance is N x 3pF, where "N" is the number of switches connected in parallel. The pole will be located at:

$$\frac{1}{2\pi \times (N \times 3\text{pF} + C_{\text{STRAY}}) \times 20\Omega} \text{ MHz}$$

CSTRAY = Stray capacitance at the interconnect

If the maximum number of switches that may be connected while still maintaining bandwidth is less than your system requirements, use a unity-gain buffer amplifier to isolate the switch from the remainder of the inputs.
