description

The TPS3510/1 is designed to minimize external components of personal-computer switching power supply systems. It provides protection circuits, power good indicator, fault protection output ($\overline{\text{FPO}}$) and $\overline{\text{PSON}}$ control.

Oversvoltage protection (OVP) monitors 3.3 V, 5 V, and 12 V (12-V signal detects via V_{DD} pin). Undersvoltage protection (UVP) monitors 3.3 V and 5 V. When an OV or UV condition is detected, the power good output (PGO) is set to low and $\overline{\text{FPO}}$ is latched high. $\overline{\text{PSON}}$ from low to high resets the protection latch. UVP function is enabled 75 ms after $\overline{\text{PSON}}$ is set low and debounced. Furthermore, there is a 2.3-ms delay (and an additional 38-ms debounce) at turnoff. There is no delay during turnon.

Power good feature monitors PGI, 3.3 V and 5 V and issues a power good signal when the output is ready.

The TPS3510/1 is characterized for operation from -40°C to 85°C .

typical application

Please be aware that an important notice concerning availability, standard warranty, and use in critical applications of Texas Instruments semiconductor products and disclaimers thereto appears at the end of this data sheet.

PRODUCTION DATA information is current as of publication date. Products conform to specifications per the terms of Texas Instruments standard warranty. Production processing does not necessarily include testing of all parameters.

detailed description

power good and power good delay

A PC power supply is commonly designed to provide a power-good signal, which is defined by the computer manufacturers. PGO is a power-good signal and should be asserted high by the PC power supply to indicate that the 5-V and 3.3-V outputs are above the under-voltage threshold limit. At this time the converter should be able to provide enough power to ensure continuous operation within the specification. Conversely, when either the 5-V or the 3.3-V output voltages fall below the under-voltage threshold, or when ac power has been removed for a time sufficiently long so that power supply operation is no longer ensured, PGO should be de-asserted to a low state.

Figure 1 represents the timing characteristics of the power good (PGO), dc enable ($\overline{\text{PSON}}$), and the 5 V/3.3 V supply rails.

Figure 1. Timing of $\overline{\text{PSON}}$ and PGO

Although there is no requirement to meet specific timing parameters, the following signal timings are recommended:

$$2 \text{ ms} \leq t_2 \leq 20 \text{ ms}, 100 \text{ ms} < t_3 < 2000 \text{ ms}, t_4 > 1 \text{ ms}, t_5 \leq 10 \text{ ms}$$

Furthermore motherboards should be designed to comply with the previously recommended timing. If timings other than these are implemented or required, this information should be clearly specified.

The TPS3510/1 family of power-supply supervisors provides a power-good output (PGO) for the 3.3-V and 5-V supply voltage rails and a separate power-good input (PGI). An internal timer is used to generate a power-good delay. If the voltage signals at PGI, VS33, and VS5 rise above the under-voltage threshold, the open-drain power-good output (PGO) goes high after a delay of 150 ms or 300 ms. When the PGI voltage or either the 3.3-V and 5-V power rails drops below the under-voltage threshold, PGO is disabled immediately (after 150- μs debounce).

power supply remote on/off ($\overline{\text{PSON}}$) and fault protect output ($\overline{\text{FPO}}$)

Since the latest personal computer generation focuses on easy turnon and power saving functions, the PC power supply requires two characteristics. One is a dc power supply remote on/off function, the other is standby voltage to achieve very low power consumption of the PC system. Thus the main power needs to be shut down.

The power supply remote on/off ($\overline{\text{PSON}}$) is an active low signal that turns on all of the main power rails including 3.3 V, 5 V, -5 V, 12 V, and -12 V power rails. When this signal is held high by the PC motherboard or left open circuited, the signal of the fault protect output ($\overline{\text{FPO}}$) also goes high. Thus, the main power rails should not deliver current and should be held at 0 V.

TPS3510,TPS3511 PC POWER SUPPLY SUPERVISORS

SLVS312A – JULY 2000 – REVISED DECEMBER 2002

power supply remote on/off ($\overline{\text{PSON}}$) and fault protect output ($\overline{\text{FPO}}$)(continued)

When the $\overline{\text{FPO}}$ signal is held high due to an occurring fault condition, the fault status is latched and the outputs of the main power rails should not deliver current but are held at 0 V. Toggling the power supply remote on/off ($\overline{\text{PSON}}$) from low to high resets the fault-protection latch. During this fault condition only the standby power is not affected.

When $\overline{\text{PSON}}$ goes from high to low or low to high, the 38-ms debounce block is active to avoid a glitch on the input that disables/enables the $\overline{\text{FPO}}$ output. During this period the under-voltage function is disabled for 75 ms to prevent turnon failure. At turnoff, there is an additional delay of 2.3 ms from $\overline{\text{PSON}}$ to $\overline{\text{FPO}}$.

Power should be delivered to the rails only if the $\overline{\text{PSON}}$ signal is held at ground potential, thus $\overline{\text{FPO}}$ is active-low. The $\overline{\text{FPO}}$ pin can be connected to 5 V (or up to 15 V) through a pullup resistor.

undervoltage protection

The TPS3510/1 provides under-voltage protection (UVP) for the 3.3-V and 5-V rails. When an undervoltage condition appears at either one of the 3.3-V (VS33) or 5-V (VS5) input pins for more than 146 μs , the $\overline{\text{FPO}}$ output goes high and PGO goes low. Also, this fault condition is latched until $\overline{\text{PSON}}$ is toggled from low to high or V_{DD} is removed.

The need for undervoltage protection is often overlooked in off-line switching power supply system design. But it is very important in battery-powered or hand-held equipment since the TTL or CMOS logic often results in malfunction.

In flyback or forward-type off-line switching power supplies, usually designed for low power, the overload protection design is very simple. Most of these types of power supplies are only sensing the input current for an overload condition. The trigger point needs to be set much higher than the maximum load in order to prevent false turnon.

However, this causes one critical problem. If the connected load is larger than the maximum allowable load but smaller than the trigger point, the system always becomes overheated with failure and damage occurring.

overvoltage protection

The overvoltage protection (OVP) of TPS3510/1 monitors 3.3 V, 5 V, and 12 V (12 V is sensed via the V_{DD} pin). When an overvoltage condition appears at one of the 3.3-V, 5-V, or 12-V input pins for more than 73 μs , the $\overline{\text{FPO}}$ output goes high and PGO goes low. Also, this fault condition is latched until $\overline{\text{PSON}}$ is toggled from low to high or V_{DD} is removed. During fault conditions, most power supplies have the potential to deliver higher output voltages than those normally specified or required. In unprotected equipment, it is possible for output voltages to be high enough to cause internal or external damage of the system. To protect the system under these abnormal conditions, it is common practice to provide overvoltage protection within the power supply.

Because TTL and CMOS circuits are very vulnerable to overvoltages, it is becoming industry standard to provide overvoltage protection on all 3.3-V and 5-V outputs. However, not only the 3.3-V and 5-V rails for the logic circuits on the motherboard need to be protected, but also the 12-V peripheral devices such as the hard disk, floppy disk, and CD-ROM players etc., need to be protected.

short-circuit power supply turnon

During safety testing the power supply might have tied the output voltage direct to ground. If this happens during the normal operating, this is called a short-circuit or over-current condition. When it happens before the power supply turns on, this is called a short-circuit power supply turnon. It can happen during the design period, in the production line, at quality control inspection or at the end user. The TPS3510/1 provides an undervoltage protection function with a 75-ms delay after $\overline{\text{PSON}}$ is set low.
