TQ PACKAGE
100 LEAD TQFP
CASE 983A–01

The MCM69D618 is a 1M–bit static random access memory, organized as 64K words of 18 bits. It features common data input and data output buffers and incorporates input and output registers on–board with high speed SRAM.

The MCM69D618 allows the user to concurrently perform reads, writes, or pass–through cycles in combination on the two data ports. The two address ports (AX, AY) determine the read or write locations for their respective data ports (DQX, DQY).

The synchronous design allows for precise cycle control with the use of an external single clock (K). All signal pins except output enables (GX, GY) are registered on the rising edge of clock (K).

The pass–through feature allows data to be passed from one port to the other, in either direction. The PTX input must be asserted to pass data from port X to port Y. The PTY will likewise pass data from port Y to port X. A pass–through operation takes precedence over a read operation.

For the case when AX and AY are the same, certain protocols are followed. If both ports are read, the reads occur normally. If one port is written and the other is read, the read from the array will occur before the data is written. If both ports are written, only the data on DQY will be written to the array.

This device contains circuitry to protect the inputs against damage due to high static voltages or electric fields; however, it is advised that normal precautions be taken to avoid application of any voltage higher than maximum rated voltages to these high–impedance circuits.
