

## LM1290

### Autosync Horizontal Deflection Processor

#### General Description

The LM1290 is a high-performance, low-cost deflection solution for autosync monitors.

The LM1290 provides full autosync capability, DC controls and complete freedom from manufacturing trims. Its continuous capture range is from 22 kHz to 110 kHz (1:5). Mode change frequency ramping, for protection of the horizontal deflection output transistor, is programmable by using an external capacitor.

Together with the National Semiconductor LM1296 Raster Geometry Correction System for Multi-Frequency Displays, excellent performance is offered. The two-chip solution provides the advantage of good jitter performance, simplified board layout, and lower system cost.

The LM1290 is packaged in a 14-pin plastic DIP package.

#### Features

- Full autosync—22 kHz to 110 kHz with no component switching or external adjustments
- No manufacturing trims needed—internal VCO capacitor trimmed on chip
- Sample-and-hold circuit for fast top-of-screen phase recovery, even when using composite sync
- DC-controlled H phase and duty cycle
- Resistor-programmable minimum VCO frequency
- Excellent jitter performance
- X-ray input disables H drive until  $V_{CC}$  powered down
- Low  $V_{CC}$  disables H drive ( $V_{CC} < 8.5V$ )
- H output transistor protected against accidental turn on during flyback
- Capacitor-programmable frequency ramping,  $df_{VCO}/dt$ , protects H output transistor during scanning mode changes

**Note 1:** Absolute Maximum Ratings indicate limits beyond which damage to the device may occur.

**Note 2:** Operating Ratings indicate conditions for which the device is functional, but do not guarantee specific performance limits. For guaranteed specifications and test conditions, see the Electrical Characteristics. The guaranteed specifications apply only for the test conditions listed. Some performance characteristics may degrade when the device is not operated under the listed test conditions.

**Note 3:** All voltages are measured with respect to GND, unless otherwise specified.

**Note 4:** The maximum power dissipation must be derated at elevated temperatures and is dictated by  $T_{JMAX}$ ,  $\theta_{JA}$  and the ambient temperature,  $T_A$ . The maximum allowable power dissipation at any elevated temperature is  $P_D = (T_{JMAX} - T_A)/\theta_{JA}$  or the number given in the Absolute Maximum Ratings, whichever is lower. For this device,  $T_{JMAX} = 150^\circ\text{C}$ . The typical thermal resistance ( $\theta_{JA}$ ) of the LM1290N is  $75^\circ\text{C/W}$ .

**Note 5:** Human Body model, 100 pF capacitor discharged through a 1.5 k $\Omega$  resistor.

**Note 6:** Typical specifications are at  $T_A = 25^\circ\text{C}$  and represent most likely parametric norm.

**Note 7:** Tested limits are guaranteed to National's AOQL (Average Outgoing Quality Level).

**Note 8:** The standard deviation,  $\sigma$ , of the flyback pulse period is measured with a HP 53310A Modulation Domain Analyzer. Peak-to-peak jitter of the flyback pulse is defined by  $6\sigma$ .

**Note 9:** A positive phase value represents a phase lead of the flyback pulse peak with reference to the center of H sync.

**Note 10:** The duty cycle is measured under the conditions of free run with  $I_1 = -100\text{ }\mu\text{A}$ ,  $T_{FBP} = 3\text{ }\mu\text{s}$  and  $T_d = 3.5\text{ }\mu\text{s}$  where  $T_{FBP}$  and  $T_d$  are the flyback pulse width and the turn off delay of the H deflection output transistor respectively.

**Note 11:**  $T_H$  is defined as the total time of one horizontal line.

## Pin Descriptions

See Figure 4 through Figure 10 for input and output schematics.

**Pin 1— $f_{\text{MIN}}$ :** A resistor from this pin to ground sets the free run frequency of the LM1290. The free run frequency should be set typically as:

$$f_{\text{MIN}} = 0.85(f_{\text{MINLOCK}}) - 2 \text{ kHz}$$

where  $f_{\text{MINLOCK}}$  is the minimum lock frequency required for the application. The resistance required to set this frequency is approximately:

$$R_{\text{MIN}} \approx \frac{5.475 \times 10^8}{f_{\text{MIN}}} - 500 \Omega$$

For example, to find  $R_{\text{MIN}}$  for VGA which has  $f_{\text{MINLOCK}} = 31.469 \text{ kHz}$ ,

$$f_{\text{MIN}} = 0.85(31.469 \text{ kHz}) - 2 \text{ kHz} = 24749$$

$$R_{\text{MIN}} \approx \frac{5.475 \times 10^8}{24749} - 500 = 21622 \Omega$$

Rounding to the closest standard 1% resistor gives  $R_{\text{MIN}} = 21.5 \text{ k}\Omega$ .

**Pin 2—H/HV POLARITY:** A  $0.1 \mu\text{F}$  capacitor is connected from this pin to ground for detecting the polarity of H/HV sync at pin 3. A low logic level at pin 2 indicates active-high H/HV sync to pin 3, a high level indicates active-low. See Figure 4 for the output schematic.

**Pin 3—H/HV SYNC:** This input pin accepts DC-coupled H or composite sync of either polarity. For best noise immunity, a resistor of  $2 \text{ k}\Omega$  or less should be connected from this pin to pin 8 (GND) via a short path. See Figure 5 for the input schematic.

**Pin 4—DUTY CYCLE:** A DC voltage applied to this pin sets the duty cycle of the H DRIVE output (pin 7), with a range of approximately 30% to 70%. 2V sets the duty cycle to approximately 50%. See Figure 6 for the input schematic.

**Pin 5—X-RAY:** This pin is for monitoring CRT anode voltage. If the input voltage exceeds an internal threshold, H

DRIVE output (pin 7) is latched high.  $V_{\text{CC}}$  has to be reduced to below approximately 2V to clear the latched condition, i.e., power must be turned off. See Figure 7 for the input schematic.

**Pin 6—FLYBACK:** Input pin for phase detector 2. For best operation, the flyback peak should be at least 5V but not greater than  $V_{\text{CC}}$ . Any pulse width greater than  $1.5 \mu\text{s}$  is acceptable. See Figure 8 for the input schematic.

**Pin 7—H DRIVE:** This is an open-collector output which provides the drive pulse for the high power deflection circuit. The pulse duty cycle is controlled by pin 4. Polarity convention: Horizontal deflection output transistor is on when H DRIVE OUT is low. See Figure 9 for the output schematic.

**Pin 8—GND:** System ground. For best jitter performance, all bypass capacitors should be connected to this pin via short paths.

**Pin 9—PD2 FILTER:** The low-pass filter cap of between  $0.01 \mu\text{F}$  to  $1 \mu\text{F}$  for the output of phase detector 2 is connected from this pin to pin 8 (GND) via a short path. A smaller value increases the response.

**Pin 10—PHASE:** A DC control voltage applied to this pin sets the phase of the flyback pulse with respect to the center of H sync. See Figure 10 for the input schematic.

**Pin 11—FVC FILTER:** A  $1 \mu\text{F}$  capacitor is connected from this pin to pin 8 (GND) via a short path.

**Pin 12—PD1 OUT/VCO IN:** Phase detector 1 has a gated charge pump output which requires an external low-pass filter. For best jitter performance, the filter should be grounded to pin 8 (GND) via a short path. If a voltage source is applied to this pin, the phase detector is disabled and the VCO can be controlled directly.

**Pin 13— $V_{\text{REF}}$ :** This is the decoupling pin for the internal 8.2V reference. It should be decoupled to pin 8 (GND) via a short path with a cap of at least  $470 \mu\text{F}$ . Do not load this pin.

**Pin 14— $V_{\text{CC}}$ :** 12V nominal power supply pin. This pin should be decoupled to pin 8 (GND) via a short path with a cap of at least  $47 \mu\text{F}$ .

## Application Hints

1. **Phase Control for Geometry Correction:** Pin 10 (PHASE) is designed to control static phase (picture horizontal position) as well as dynamic phase for geometry correction. Complete control of static and dynamic phase can be achieved by superposing a correction waveform (Sawtooth and/or parabola) on the DC control voltage at pin 10 (see Figure 12).
2. **Programmable Frequency Ramping:** H frequency transitions from high to low present a special problem for deflection output stages without current limiting. If, during such a transition, the output transistor on-time increases excessively before the B+ voltage has decreased to its final level, then the deflection inductor current ramps too high and the induced flyback pulse can exceed the breakdown voltage,  $BV_{CEX}$ , of the output transistor. To prevent this, the rate of change of the VCO frequency must be limited.

Consider a scanning mode transition at  $t = 0$  from  $f_1$  to  $f_2$ . The VCO frequency as a function of time,  $f_{VCO}(t)$ , is described by the equation,

$$f_{VCO}(t) \equiv f_1 + (f_2 - f_1) (1 - \exp(-t/\tau)),$$

where  $\tau = 40 \times 10^3 \times C_{FVC}$ .

The above equation can be used to predict VCO behavior during frequency transitions, but in practice the value of  $C_{FVC}$  is most easily determined empirically. In general, large values minimize the chance of exceeding  $BV_{CEX}$ , but generate long PLL capture times.

3. **Phase Voltage Range vs Delay Time:** The recommended phase voltage range to use on pin 10 (PHASE) depends on the delay time of the deflection output stage. Delay time is defined as the time from the rising edge of H Drive to the center of flyback. For best performance the phase voltage range should be in the unshaded area of Figure 11.

**FIGURE 11.**

## Typical Application

\*Actual value depends on the application and the ambient noise level inside the monitor.

## LIFE SUPPORT POLICY

NATIONAL'S PRODUCTS ARE NOT AUTHORIZED FOR USE AS CRITICAL COMPONENTS IN LIFE SUPPORT DEVICES OR SYSTEMS WITHOUT THE EXPRESS WRITTEN APPROVAL OF THE PRESIDENT AND GENERAL COUNSEL OF NATIONAL SEMICONDUCTOR CORPORATION. As used herein:

1. Life support devices or systems are devices or systems which, (a) are intended for surgical implant into the body, or (b) support or sustain life, and whose failure to perform when properly used in accordance with instructions for use provided in the labeling, can be reasonably expected to result in a significant injury to the user.
2. A critical component is any component of a life support device or system whose failure to perform can be reasonably expected to cause the failure of the life support device or system, or to affect its safety or effectiveness.
