

LMV721/LMV722

10MHz, Low Noise, Low Voltage, and Low Power Operational Amplifier

General Description

The LMV721 (Single) and LMV722 (Dual) are low noise, low voltage, and low power op amps, that can be designed into a wide range of applications. The LMV721/LMV722 has a unity gain bandwidth of 10MHz, a slew rate of 5V/us, and a quiescent current of 930uA/amplifier at 2.2V.

The LMV721/722 are designed to provide optimal performance in low voltage and low noise systems. They provide rail-to-rail output swing into heavy loads. The input common-mode voltage range includes ground, and the maximum input offset voltage are 3.5mV (Over Temp.) for the LMV721/LMV722. Their capacitive load capability is also good at low supply voltages. The operating range is from 2.2V to 5.5V.

The chip is built with National's advanced Submicron Silicon-Gate BiCMOS process. The single version, LMV721, is available in 5 pin SOT23-5 and a SC-70 (new) package. The dual version, LMV722, is available in a SO-8, MSOP-8 and 8-pin LLP package.

Features

(For Typical, 5 V Supply Values; Unless Otherwise Noted)

- Guaranteed 2.2V and 5.0V Performance
- Low Supply Current LMV721/2 930μA/amplifier @2.2V
- High Unity-Gain Bandwidth 10MHz
- Rail-to-Rail Output Swing
 - @600Ω load 120mV from either rail at 2.2V
 - @2kΩ load 50mV from either rail at 2.2V
- Input Common Mode Voltage Range Includes Ground
- Silicon Dust™, SC70-5 Package 2.0x2.0x1.0 mm
- Miniature packaging: LLP-8 2.5mm x 3mm x 0.8mm
- Input Voltage Noise 9 nV/√Hz @ f = 1KHz

Applications

- Cellular and Cordless Phones
- Active Filter and Buffers
- Laptops and PDAs
- Battery Powered Electronics

A Battery Powered Microphone Preamplifier

10092244

Absolute Maximum Ratings (Note 1)

If Military/Aerospace specified devices are required, please contact the National Semiconductor Sales Office/Distributors for availability and specifications.

ESD Tolerance (Note 2)	
Human Body Model	2000V
Machine Model	100V
Differential Input Voltage	± Supply Voltage
Supply Voltage ($V^+ - V^-$)	5.5V
Soldering Information	
Infrared or Convection (20 sec.)	235°C
Storage Temp. Range	-65°C to 150°C
Junction Temperature (Note 4)	150°C

Operating Ratings (Note 3)

Supply Voltage	2.2V to 5.0V
Temperature Range	-40°C ≤ T _J ≤ 85°C
Thermal Resistance (θ _{JA})

Note 1: Absolute Maximum Ratings indicate limits beyond which damage to the device may occur. Operating Ratings indicate conditions for which the device is intended to be functional, but specific performance is not guaranteed. For guaranteed specifications and the test conditions, see the Electrical Characteristics.

Note 2: Human body model, 1.5 k Ω in series with 100 pF. Machine model, 200 Ω in series with 100 pF.

Note 3: Applies to both single-supply and split-supply operation. Continuous short circuit operation at elevated ambient temperature can result in exceeding the maximum allowed junction temperature of 150°C. Output currents in excess of 30 mA over long term may adversely affect reliability.

Note 4: The maximum power dissipation is a function of $T_{J(\text{max})}$, θ_{JA} , and T_A . The maximum allowable power dissipation at any ambient temperature is $P_D = (T_{J(\text{max})} - T_A) / \theta_{JA}$. All numbers apply for packages soldered directly into a PC board.

Note 5: Typical Values represent the most likely parametric norm.

Note 6: All limits are guaranteed by testing or statistical analysis.

Note 7: Connected as voltage follower with 1V step input. Number specified is the slower of the positive and negative slew rate.

Application Notes

1.0 Benefits of the LMV721/722 Size.

The small footprints of the LMV721/722 packages save space on printed circuit boards, and enable the design of smaller electronic products, such as cellular phones, pagers, or other portable systems. The low profile of the LMV721/722 make them possible to use in PCMCIA type III cards.

Signal Integrity. Signals can pick up noise between the signal source and the amplifier. By using a physically smaller amplifier package, the LMV721/722 can be placed closer to the signal source, reducing noise pickup and increasing signal integrity.

Simplified Board Layout. These products help you to avoid using long pc traces in your pc board layout. This means that no additional components, such as capacitors and resistors, are needed to filter out the unwanted signals due to the interference between the long pc traces.

Low Supply Current. These devices will help you to maximize battery life. They are ideal for battery powered systems.

Low Supply Voltage. National provides guaranteed performance at 2.2V and 5V. These guarantees ensure operation throughout the battery lifetime.

Rail-to-Rail Output. Rail-to-rail output swing provides maximum possible dynamic range at the output. This is particularly important when operating on low supply voltages.

Input Includes Ground. Allows direct sensing near GND in single supply operation.

Protection should be provided to prevent the input voltages from going negative more than $-0.3V$ (at $25^{\circ}C$). An input clamp diode with a resistor to the IC input terminal can be used.

2.0 Capacitive Load Tolerance

The LMV721/722 can directly drive 4700pF in unity-gain without oscillation. The unity-gain follower is the most sensitive configuration to capacitive loading. Direct capacitive loading reduces the phase margin of amplifiers. The combination of the amplifier's output impedance and the capacitive load induces phase lag. This results in either an under-damped pulse response or oscillation. To drive a heavier capacitive load, circuit in *Figure 1* can be used.

FIGURE 1. Indirectly Driving A capacitive Load Using Resistive Isolation

In *Figure 1*, the isolation resistor R_{ISO} and the load capacitor C_L form a pole to increase stability by adding more phase margin to the overall system. The desired performance depends on the value of R_{ISO} . The bigger the R_{ISO} resistor value, the more stable V_{OUT} will be. *Figure 2* is an output waveform of *Figure 1* using $100k\Omega$ for R_{ISO} and $2000\mu F$ for C_L .

FIGURE 2. Pulse Response of the LMV721 Circuit in Figure 1

The circuit in *Figure 3* is an improvement to the one in *Figure 1* because it provides DC accuracy as well as AC stability. If there were a load resistor in *Figure 1*, the output would be voltage divided by R_{ISO} and the load resistor. Instead, in *Figure 3*, R_F provides the DC accuracy by using feed-forward techniques to connect V_{IN} to R_L . Caution is needed in choosing the value of R_F due to the input bias current of the LMV721/722. C_F and R_{ISO} serve to counteract the loss of phase margin by feeding the high frequency component of the output signal back to the amplifier's inverting input, thereby preserving phase margin in the overall feedback loop. Increased capacitive drive is possible by increasing the value of C_F . This in turn will slow down the pulse response.

FIGURE 3. Indirectly Driving A Capacitive Load with DC Accuracy

3.0 Input Bias Current Cancellation

The LMV721/722 family has a bipolar input stage. The typical input bias current of LMV721/722 is 260nA with 5V supply. Thus a $100k\Omega$ input resistor will cause 26mV of error voltage. By balancing the resistor values at both inverting and non-inverting inputs, the error caused by the amplifier's input bias current will be reduced. The circuit in *Figure 4* shows how to cancel the error caused by input bias current.

Application Notes (Continued)

FIGURE 4. Cancelling the Error Caused by Input Bias Current

4.0 Typical Single-Supply Application Circuits

4.1 Difference amplifier

The difference amplifier allows the subtraction of two voltages or, as a special case, the cancellation of a signal common to two inputs. It is useful as a computational amplifier, in making a differential to single-ended conversion or in rejecting a common mode signal.

$$V_{OUT} = \left(\frac{R_1 + R_2}{R_3 + R_4} \right) \frac{R_4}{R_1} V_2 - \frac{R_2}{R_1} V_1 + \left(\frac{R_1 + R_2}{R_3 + R_4} \right) \frac{R_3}{R_1} \cdot \frac{V^+}{2}$$

for $R_1 = R_3$ and $R_2 = R_4$

$$V_{OUT} = \frac{R_2}{R_1} (V_2 - V_1) + \frac{V^+}{2}$$

FIGURE 5. Difference Application

4.2 Instrumentation Circuits

The input impedance of the previous difference amplifier is set by the resistor R_1 , R_2 , R_3 and R_4 . To eliminate the problems of low input impedance, one way is to use a voltage follower ahead of each input as shown in the following two instrumentation amplifiers.

4.2.1 Three-op-amp Instrumentation Amplifier

The LMV721/722 can be used to build a three-op-amp instrumentation amplifier as shown in *Figure 6*

FIGURE 6. Three-op-amp Instrumentation Amplifier

The first stage of this instrumentation amplifier is a differential-input, differential-output amplifier, with two voltage followers. These two voltage followers assure that the input impedance is over 100MΩ. The gain of this instrumentation amplifier is set by the ratio of R_2/R_1 . R_3 should equal R_1 and R_4 equal R_2 . Matching of R_3 to R_1 and R_4 to R_2 affects the CMRR. For good CMRR over temperature, low drift resistors should be used. Making R_4 slightly smaller than R_2 and adding a trim pot equal to twice the difference between R_2 and R_4 will allow the CMRR to be adjusted for optimum.

4.2.2 Two-op-amp Instrumentation Amplifier

A two-op-amp instrumentation amplifier can also be used to make a high-input impedance DC differential amplifier (*Figure 7*). As in the two-op-amp circuit, this instrumentation amplifier requires precise resistor matching for good CMRR. R_4 should equal to R_1 and R_3 should equal R_2 .

$$V_0 = \left(1 + \frac{R_4}{R_3} \right) (V_2 - V_1), \text{ where } R_1 = R_4 \text{ and } R_2 = R_3$$

As shown: $V_0 = 2(V_2 - V_1)$

FIGURE 7. Two-op-amp Instrumentation Amplifier

4.3 Single-Supply Inverting Amplifier

There may be cases where the input signal going into the amplifier is negative. Because the amplifier is operating in single supply voltage, a voltage divider using R_3 and R_4 is implemented to bias the amplifier so the input signal is within the input common-mode voltage range of the amplifier. The capacitor C_1 is placed between the inverting input and resistor R_1 to block the DC signal going into the AC signal source, V_{IN} . The values of R_1 and C_1 affect the cutoff frequency, $f_c = 1/2\pi R_1 C_1$.

Application Notes (Continued)

As a result, the output signal is centered around mid-supply (if the voltage divider provides $V^+/2$ at the non-inverting input). The output can swing to both rails, maximizing the signal-to-noise ratio in a low voltage system.

10092223

$$V_{OUT} = -\frac{R_2}{R_1} V_{IN}$$

FIGURE 8. Single-Supply Inverting Amplifier

4.4 Active Filter

4.4.1 Simple Low-Pass Active Filter

The simple low-pass filter is shown in *Figure 9*. Its low-pass frequency gain ($\omega \rightarrow 0$) is defined by $-R_3/R_1$. This allows low-frequency gains other than unity to be obtained. The filter has a -20dB/decade roll-off after its corner frequency f_c . R_2 should be chosen equal to the parallel combination of R_1 and R_3 to minimize error due to bias current. The frequency response of the filter is shown in *Figure 10*.

10092224

$$A_L = -\frac{R_3}{R_1}$$

$$f_c = \frac{1}{2\pi R_3 C_1}$$

$$R_2 = R_1 \parallel R_3$$

FIGURE 9. Simple Low-Pass Active Filter

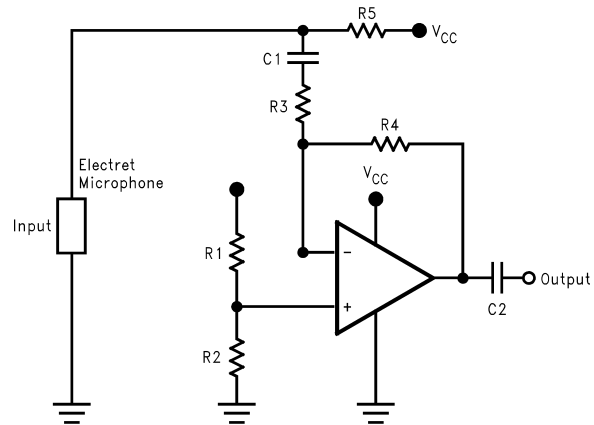

FIGURE 10. Frequency Response of Simple Low-pass Active Filter in *Figure 9*

Note that the single-op-amp active filters are used in to the applications that require low quality factor, $Q(\leq 10)$, low frequency ($\leq 5\text{kHz}$), and low gain (≤ 10), or a small value for the product of gain times $Q(\leq 100)$. The op amp should have an open loop voltage gain at the highest frequency of interest at least 50 times larger than the gain of the filter at this frequency. In addition, the selected op amp should have a slew rate that meets the following requirement:

$$\text{Slew Rate} \geq 0.5 \times (\omega_H V_{OPP}) \times 10^{-6} \text{V}/\mu\text{sec}$$

Where ω_H is the highest frequency of interest, and V_{OPP} is the output peak-to-peak voltage.

10092244

FIGURE 11. A Battery Powered Microphone Preamplifier

Here is a LMV721 used as a microphone preamplifier. Since the LMV721 is a low noise and low power op amp, it makes it an ideal candidate as a battery powered microphone preamplifier. The LMV721 is connected in an inverting configuration. Resistors, $R_1 = R_2 = 4.7\text{k}\Omega$, sets the reference half way between $V_{CC} = 3\text{V}$ and ground. Thus, this configures the op amp for single supply use. The gain of the preamplifier, which is 50 (34dB), is set by resistors $R_3 = 10\text{k}\Omega$ and $R_4 = 500\text{k}\Omega$. The gain bandwidth product for the LMV721 is 10 MHz. This is sufficient for most audio application since the audio range is typically from 20 Hz to 20kHz. A resistor $R_5 = 5\text{k}\Omega$ is used to bias the electret microphone. Capacitors $C_1 = C_2 = 4.7\mu\text{F}$ placed at the input and output of the op amp to block out the DC voltage offset.

Connection Diagrams

Note: LLP-8 exposed DAP can be electrically connected to ground for improved thermal performance.

LIFE SUPPORT POLICY

NATIONAL'S PRODUCTS ARE NOT AUTHORIZED FOR USE AS CRITICAL COMPONENTS IN LIFE SUPPORT DEVICES OR SYSTEMS WITHOUT THE EXPRESS WRITTEN APPROVAL OF THE PRESIDENT AND GENERAL COUNSEL OF NATIONAL SEMICONDUCTOR CORPORATION. As used herein:

1. Life support devices or systems are devices or systems which, (a) are intended for surgical implant into the body, or (b) support or sustain life, and whose failure to perform when properly used in accordance with instructions for use provided in the labeling, can be reasonably expected to result in a significant injury to the user.
2. A critical component is any component of a life support device or system whose failure to perform can be reasonably expected to cause the failure of the life support device or system, or to affect its safety or effectiveness.
