

FEATURES

- Monolithic 40 MSPS Converter
- 175 mW Power Dissipation
- On-Chip Track-and-Hold
- Single +5 V Power Supply
- TTL/CMOS Outputs
- 5 pF Input Capacitance
- Low Cost
- Tri-State Output Buffers
- High ESD Protection: 3,500 V Minimum
- Selectable +3 V or +5 V Logic I/O

GENERAL DESCRIPTION

The SPT7734 is a 8-bit monolithic, low cost, ultralow power analog-to-digital converter capable of minimum word rates of 40 MSPS. The on-chip track-and-hold function assures very good dynamic performance without the need for external components. The input drive requirements are minimized due to the SPT7734's low input capacitance of only 5 pF.

Power dissipation is extremely low at only 175 mW typical at 40 MSPS with a power supply of +5.0 V. The digital outputs

APPLICATIONS

- All High-Speed Applications Where Low Power Dissipation is Required
- Video Imaging
- Medical Imaging
- Radar Receivers
- IR Imaging
- Digital Communications

are +3 V or +5 V, and are user selectable. The SPT7734 has incorporated proprietary circuit design and CMOS processing technologies to achieve its advanced performance. Inputs and outputs are TTL/CMOS compatible to interface with TTL/CMOS logic systems. Output data format is straight binary.

The SPT7734 is available in 28-lead SOIC and 32-lead small (7 mm square) TQFP packages over the commercial temperature range.

TEST LEVEL CODES

All electrical characteristics are subject to the following conditions:

All parameters having min/max specifications are guaranteed. The Test Level column indicates the specific device testing actually performed during production and Quality Assurance inspection. Any blank section in the data column indicates that the specification is not tested at the specified condition.

TEST LEVEL

TEST PROCEDURE

I	100% production tested at the specified temperature.
II	100% production tested at $T_A = 25$ °C, and sample tested at the specified temperatures.
III	QA sample tested only at the specified temperatures.
IV	Parameter is guaranteed (but not tested) by design and characterization data.
V	Parameter is a typical value for information purposes only.
VI	100% production tested at $T_A = 25$ °C. Parameter is guaranteed over specified temperature range.

TYPICAL INTERFACE CIRCUIT

Very few external components are required to achieve the stated device performance. Figure 1 shows the typical interface requirements when using the SPT7734 in normal circuit operation. The following sections provide descriptions of the major functions and outline critical performance criteria to consider for achieving the optimal device performance.

Figure 1 - Typical Interface Circuit

- NOTES: 1) FB3 is to be located as closely to the device as possible.
2) There should be no additional connections to the right of FB1 and FB2.
3) All capacitors are 0.1 μ F surface-mount unless otherwise specified.
4) FB1, FB2 and FB3 are 10 μ H inductors or ferrite beads.

POWER SUPPLIES AND GROUNDING

Fairchild suggests that both the digital and the analog supply voltages on the SPT7734 be derived from a single analog supply as shown in figure 1. A separate digital supply should be used for all interface circuitry. Fairchild suggests using this power supply configuration to prevent a possible latch-up condition on power up.

OPERATING DESCRIPTION

The general architecture for the CMOS ADC is shown in the block diagram. The design contains 16 identical successive approximation ADC sections, all operating in parallel, a 16-phase clock generator, an 9-bit 16:1 digital output multiplexer, correction logic, and a voltage reference generator which provides common reference levels for each ADC section.

The high sample rate is achieved by using multiple SAR ADC sections in parallel, each of which samples the input signal in sequence. Each ADC uses 16 clock cycles to complete a conversion. The clock cycles are allocated as follows:

Table II - Clock Cycles

Clock	Operation
1	Reference zero sampling
2	Auto-zero comparison
3	Auto-calibrate comparison
4	Input sample
5-15	9-bit SAR conversion
16	Data transfer

The 16 phase clock, which is derived from the input clock, synchronizes these events. The timing signals for adjacent ADC sections are shifted by one clock cycle so that the analog input is sampled on every cycle of the input clock by exactly one ADC section. After 16 clock periods, the timing cycle repeats. The latency from analog input sample to the corresponding digital output is 12 clock cycles.

- Since only 16 comparators are used, a huge power savings is realized.
- The auto-zero operation is done using a closed loop system that uses multiple samples of the comparators response to a reference zero.
- The auto-calibrate operation, which calibrates the gain of the MSB reference and the LSB reference, is also done with a closed loop system. Multiple samples of the gain error are integrated to produce a calibration voltage for each ADC section.
- Capacitive displacement currents, which can induce sampling error, are minimized since only one comparator samples the input during a clock cycle.
- The total input capacitance is very low since sections of the converter which are not sampling the signal are isolated from the input by transmission gates.

VOLTAGE REFERENCE

The SPT7734 requires the use of a single external voltage reference for driving the high side of the reference ladder. It must be within the range of 3 V to 5 V. The lower side of the ladder is typically tied to AGND (0.0 V), but can be run up to 2.0 V with a second reference. The analog input voltage range will track the total voltage difference measured between the ladder sense lines, V_RHS and V_RLS.

Force and sense taps are provided to ensure accurate and stable setting of the upper and lower ladder sense line voltages across part-to-part and temperature variations. By using the configuration shown in figure 2, offset and gain errors of less than ± 2 LSB can be obtained.

Pin diagram of the AD603 precision programmable gain amplifier. The diagram shows a 7-pin package with the following connections:

- Pin 1: AGND (Analog Ground)
- Pin 2: V_{RHF} (Non-inverting input of the first op-amp)
- Pin 3: V_{RHS} (Inverting input of the first op-amp)
- Pin 4: N/C (Not Connected)
- Pin 5: V_{RLS} (Non-inverting input of the second op-amp)
- Pin 6: V_{RLF} (Inverting input of the second op-amp)
- Pin 7: V_{IN} (Output of the second op-amp)

CLOCK INPUT

The SPT7734 is driven from a single-ended TTL-input clock. Because the pipelined architecture operates on the rising edge of the clock input, the device can operate over a wide range of input clock duty cycles without degrading the dynamic performance.

DIGITAL OUTPUTS

The digital outputs (D0-D8) are driven by a separate supply (OV_{DD}) ranging from +3 V to +5 V. This feature makes it possible to drive the SPT7734's TTL/CMOS-compatible outputs with the user's logic system supply. The format of the output data (D0-D7) is straight binary. (See table III.) The outputs are latched on the rising edge of CLK. These outputs can be switched into a tri-state mode by bringing $\overline{EN}$ high.

Table III - Output Data Information

ANALOG INPUT	OVERRANGE D8	OUTPUT CODE D7-D0
+F.S. + 1/2 LSB	1	1111 1111
+F.S. -1/2 LSB	0	1111 1110
+1/2 F.S.	0	0000 0000
+1/2 LSB	0	0000 0000
0.0 V	0	0000 0000

(0 indicates the flickering bit between logic 0 and 1).

DO NOT CONNECT PINS (DNC)

There are two pins designated as Do Not Connect (DNC). These pins must be left floating for proper operation of the device.

OVERRANGE OUTPUT

The OVERRANGE OUTPUT (D8) is an indication that the analog input signal has exceeded the positive full scale input voltage by 1 LSB. When this condition occurs, D8 will switch to logic 1. All other data outputs (D0 to D7) will remain at logic 1 as long as D8 remains at logic 1. This feature makes it possible to include the SPT7734 into higher resolution systems.
