ON/OFF Operation

- ON/OFF operation is available by mounting externally D_2 and R_3 .
- When V_{ADJ} is forcibly raised above V_{REF} (1.25V TYP) by applying the external signal, the output is turned off (pass transistor of regulator is turned off). When the output is OFF, V_{ADJ} must be higher than $V_{REF MAX.}$, and at the same time must be lower than maximum rating 7V.

In OFF-state, the load current flows to R_L from V_{ADJ} through R_2 . Therefore the value of R_2 must be as high as possible.

- $V_{O'} = V_{ADJ} \times R_L / (R_L + R_2)$

occurs at the load. OFF-state equivalent circuit R_1 up to $10k\Omega$ is allowed. Select as high value of R_1 and R_2 as possible in this range. In some case, as output voltage is getting lower ($V_O < 1V$), impedance of load resistance rises. In such condition, it is sometime impossible to obtain the minimum value of $V_{O'}$. So add the dummy resistance indicated by R_D in the figure to the circuit parallel to the load.
