

### FEATURES

**Integrated Stereo Modulator & Power Stage**

**0.005% THD+N**

**101.5dB Dynamic Range**

**PSRR > 65 dB**

**R<sub>DS-ON</sub> < 0.3 Ω (per transistor)**

**Efficiency > 80% @ 5W/6 Ω**

**EMI Optimized Modulator**

**On-Off-Mute Pop Noise Suppression**

**Short Circuit Protection**

**Over-Temperature Protection**

**Low Cost DMOS Process**

### APPLICATIONS

**Flat Panel Televisions**

**Automotive Amplifiers**

**PC Audio Systems**

**Mini Components**

### GENERAL DESCRIPTION

The AD199x is a two channel Bridge Tied Load (BTL) switching audio power amplifier with integrated  $\Sigma\Delta$  modulator. The modulator accepts a 1V<sub>rms</sub> input signal (maximum power) and generates a switching waveform to drive speakers directly. One of the two modulators can control both output stages providing twice the current for single-channel applications. A digital, microcontroller-compatible interface provides control of reset, mute and PGA gain as well as output signals for thermal and over-current error conditions. The output stage can operate from supply voltages ranging from 8V to 20V. The analog modulator and digital logic operate from a 5V supply.

## FUNCTIONAL DESCRIPTION

### DEVICE ARCHITECTURE

The AD199x is an audio quality, switching amplifier with an integrated sigma-delta modulator. The power stage of the AD199x is arranged internally as four transistor pairs, which are used as two H-bridge outputs to provide stereo amplification. The transistor pairs are driven by the output of the  $\Sigma\Delta$  modulator. A user selectable non-overlap time is provided between the switching of the high side transistor and low side transistor to ensure that both transistors are never on at the same time. The AD199x implements turn on pop suppression to eliminate any pops or clicks following a reset or un-mute.

### Analog Input Section

The analog input section uses an internal amplifier to bias the input signal to the reference level. A DC blocking capacitor should be connected as shown in Figure 15 to remove any external DC bias contained in the input signal

Figure 15. Normal Operation

### The Sigma-Delta Modulator

Detailed description pending on patents pending, as well as announcements, conference proceedings and other scheduled public disclosures.

### Selecting Stereo or Mono Mode

### Driving the H-Bridge

Each channel of the switching amplifier is controlled by a 4 transistor H-bridge to give a differential output stage. The outputs of the H-bridges, OTR+, OTR-, OUTL+ and OUTL- will switch between PVDD and PGND as determined by the sigma delta modulator. The power supply that is used to drive the power stage of the AD199x should be typically in the range of +8 V to +20 V and should be capable of supplying enough current to drive the load. This power supply is connected across the PVDD and PGND pins. The feedback pins, NFR+, NFR-, NFL+ and NFL-, are used to supply negative feedback to the modulator. The pins are connected to the outputs of the H-bridge via a resistor divider network as shown in Figure 16. See the section on Selecting the Modulator Gain for more information.

External schottky diodes can be used to reduce power loss during the non-overlap time when neither of the high-side or low-side transistors is on. During this time neither transistor is

driving the OUTx pin. The nature of the inductors is to keep current flowing. For example the OUTx pin may approach and pass the PGND level to achieve this. When the voltage at the OUTx pin is 0.7V below PGND the parasitic diode associated with the low-side transistor will become forward biased and turn on. When the high-side transistor turns on the voltage at OUTx will rise to PVDD and will reverse bias the parasitic diode. However, by its nature the parasitic diode has a long reverse recovery time and current will continue to flow through it to PGND thus causing the entire circuit to draw more current than necessary. The addition of the schottky diodes prevents this happening. When the OUTx pin goes more than 0.3V below PGND the schottky diode becomes forward biased. When the high-side transistor turns on the schottky diode becomes reverse biased. The reverse recovery time of the schottky diode is significantly faster than the parasitic diode so far less current is wasted. A similar effect happens when the inductor induces a current which drives the OUTx pin above PVDD. Figure 16 shows how the external components of a system are connected to the pins of the AD199x to form the H-bridge configuration.

## AMPLIFIER GAIN

### Selecting the Modulator Gain

The AD199x modulator can be thought of as a switching analog amplifier with a voltage gain controlled by two external resistors forming a resistor divider between the OUTxx pins and PGND. The centre of the resistor divider is connected to the appropriate feedback pin NFx. Selecting the gain along with the PVDD Voltage will determine how much power can be delivered to a load for a fixed input signal. The gain of the modulator is controlled by the values of R1 and R2 (see Figure 16) according to the equation below.

$$\text{Gain} = (R1 + R2)/R2$$

The gain should be selected such that a 1Vrms input signal doesn't cause the modulator to generate an output signal which has a peak to peak value greater than 90% of PVDD. Selecting a gain that meets this criteria will ensure that the modulator remains in a stable operating condition.

Figure 16. H-Bridge Configuration

**Programmable Gain Amplifier (PGA)**

The AD199x incorporates a single-ended to differential converter for each channel in the analog front-end section. Both single-ended to differential converters feature a programmable gain amplifier with four different gain settings. The gain is set using the pins PGA1 and PGA0 as shown in Table 5. The PGA1 and PGA0 pins are continuously monitored allow the gain to be changed at any time.

**Table 5. PGA Gain Settings**

PGA1	PGA0	PGA Gain (dB)
0	0	0
0	1	6
1	0	12
1	1	18

**SYSTEM DESIGN**

**Clocking**

The AD199x has two clock pins, CLKI and CLKO which are used to configure the clocking scheme for the device. The AD199x should be driven by a clock which is  $256 \times f_s$  where  $f_s$  is the desired sampling rate. If a crystal is to be used as the clock source it should be connected across the CLKI and CLKO pins as shown in Figure 17. Crystal Connection The values and type of capacitors used will be determined by the crystal manufacturer. A square-wave clock source may be connected directly to the CLKI pin. The logic levels of the square wave should be compatible with those defined in the Digital I/O section of the specifications page.

Figure 17. Crystal Connection

**Output Transistor Non-Overlap Time**

Ipsum lorem...

**Power-up Considerations**

Careful power-up is necessary when using the AD199x to ensure correct operation and avoid possible latch-up issues. The AD199x should be powered-up with RST/PDN and MUTE held low until all the power supplies have stabilized. Once the supplies have stabilized the AD199x can be brought out of reset by bringing RST/PDN high and then MUTE can be brought

high as required.

**On/Off/Mute Pop Noise Suppression**

The AD199x features pop suppression which is activated when the part is reset or taken out of mute. The pop suppression is achieved by pulsing the power outputs to bring the outputs of the LC filter from 0V to mid-scale in a controlled fashion. This feature eliminates unwanted transients on both the outputs and the high voltage power supply.

**Thermal Protection**

The AD199x features thermal protection. When the die temperature exceeds approximately 135°C the Thermal Warning Error output (ERR1) is asserted. If the die temperature exceeds approximately 150°C the Thermal Shutdown Error output (ERR2) is asserted. If this occurs, the part shuts down to prevent damage to the part. When the die temperature drops below approximately 120°C both error outputs are negated and the part returns to normal operation.

**Over-current Protection**

The AD199x features over current or short circuit protection. If the current through any power transistors exceeds 4A the part goes into mute and the Over-current error output (ERR0) is asserted. This is a latched error and does not clear automatically. To clear the error condition and restore normal operation, the part must be either reset, or MUTE must be asserted and negated.

**Application Considerations**

Good board layout and decoupling are vital for correct operation of the AD199x. Due to the fact that the part switches high currents there is the potential for large PVDD bounce each time a transistor transitions. This can cause unpredictable operation of the part. To avoid this potential problem, close chip decoupling is essential. It is also recommended that the decoupling capacitors are placed on the same side of the board as the AD199x, and connected directly to the PVDD and PGND pins. By placing the decoupling capacitors on the other side of the board and decoupling through vias the effectiveness of the decoupling is reduced. This is because vias have inductive properties and therefore prevent very fast discharge of the decoupling capacitors. Best operation is achieved with at least one decoupling capacitor on each side of the AD199x, or optionally two capacitors per side can be used to further reduce the series resistance of the capacitor. If these decoupling recommendations cannot be followed and decoupling through vias is the only option, the vias should be made as large as possible to increase surface area, thereby reducing inductance and resistance.

OUTLINE DIMENSIONS

Figure 20. 64-Lead Frame Chip Scale Package (LFCSP)

ESD CAUTION

ESD (electrostatic discharge) sensitive device. Electrostatic charges as high as 4000 V readily accumulate on the human body and test equipment and can discharge without detection. Although this product features proprietary ESD protection circuitry, permanent damage may occur on devices subjected to high energy electrostatic discharges. Therefore, proper ESD precautions are recommended to avoid performance degradation or loss of functionality.
