

# 4-Mb (256K x 18) Flow-Through Sync SRAM

## Features

- 256K X 18 common I/O
- 3.3V -5% and +10% core power supply ( $V_{DD}$ )
- 2.5V or 3.3V I/O supply ( $V_{DDQ}$ )
- Fast clock-to-output times
  - 6.5 ns (133-MHz version)
  - 7.5 ns (117-MHz version)
  - 8.0 ns (100-MHz version)
  - 11.0ns (66-MHz version)
- Provide high-performance 2-1-1 access rate
- User-selectable burst counter supporting Intel® Pentium® interleaved or linear burst sequences
- Separate processor and controller address strobes
- Synchronous self-timed write
- Asynchronous output enable
- Offered in JEDEC-standard 100-pin TQFP and 119-ball BGA packages
- “ZZ” Sleep Mode option

## Functional Description<sup>[1]</sup>

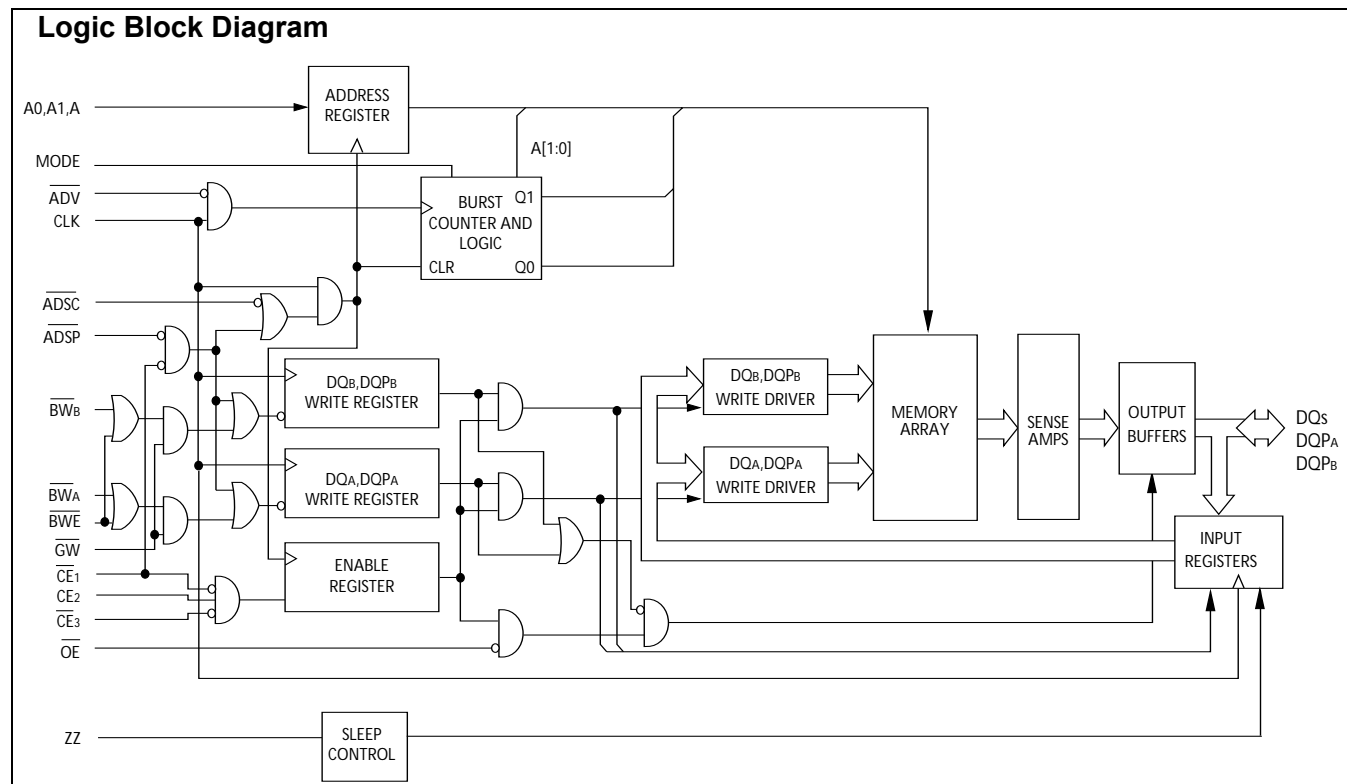

The CY7C1325F is a 262,144 x 18 synchronous cache RAM designed to interface with high-speed microprocessors with

minimum glue logic. Maximum access delay from clock rise is 6.5 ns (133-MHz version). A 2-bit on-chip counter captures the first address in a burst and increments the address automatically for the rest of the burst access. All synchronous inputs are gated by registers controlled by a positive-edge-triggered Clock Input (CLK). The synchronous inputs include all addresses, all data inputs, address-pipelining Chip Enable ( $\overline{CE}_1$ ), depth-expansion Chip Enables ( $\overline{CE}_2$  and  $\overline{CE}_3$ ), Burst Control inputs ( $\overline{ADSC}$ ,  $\overline{ADSP}$ , and  $\overline{ADV}$ ), Write Enables ( $\overline{BW}_{[A:B]}$ , and  $\overline{BWE}$ ), and Global Write ( $\overline{GW}$ ). Asynchronous inputs include the Output Enable ( $\overline{OE}$ ) and the ZZ pin.

The CY7C1325F allows either interleaved or linear burst sequences, selected by the MODE input pin. A HIGH selects an interleaved burst sequence, while a LOW selects a linear burst sequence. Burst accesses can be initiated with the Processor Address Strobe ( $\overline{ADSP}$ ) or the cache Controller Address Strobe ( $\overline{ADSC}$ ) inputs.

Addresses and chip enables are registered at rising edge of clock when either Address Strobe Processor ( $\overline{ADSP}$ ) or Address Strobe Controller ( $\overline{ADSC}$ ) are active. Subsequent burst addresses can be internally generated as controlled by the Advance pin ( $\overline{ADV}$ ).

The CY7C1325F operates from a +3.3V core power supply while all outputs may operate with either a +2.5 or +3.3V supply. All inputs and outputs are JEDEC-standard JESD8-5-compatible.

## Functional Overview

All synchronous inputs pass through input registers controlled by the rising edge of the clock. Maximum access delay from the clock rise ( $t_{CO}$ ) is 6.5 ns (133-MHz device).

The CY7C1325F supports secondary cache in systems utilizing either a linear or interleaved burst sequence. The interleaved burst order supports Pentium® and i486 processors. The linear burst sequence is suited for processors that utilize a linear burst sequence. The burst order is user-selectable, and is determined by sampling the MODE input. Accesses can be initiated with either the Processor Address Strobe (ADSP) or the Controller Address Strobe (ADSC). Address advancement through the burst sequence is controlled by the  $\overline{ADV}$  input. A two-bit on-chip wraparound burst counter captures the first address in a burst sequence and automatically increments the address for the rest of the burst access.

Byte write operations are qualified with the Byte Write Enable (BWE) and Byte Write Select ( $\overline{BW[A:B]}$ ) inputs. A Global Write Enable ( $\overline{GW}$ ) overrides all byte write inputs and writes data to all four bytes. All writes are simplified with on-chip synchronous self-timed write circuitry.

Three synchronous Chip Selects ( $\overline{CE}_1$ ,  $\overline{CE}_2$ ,  $\overline{CE}_3$ ) and an asynchronous Output Enable ( $\overline{OE}$ ) provide for easy bank selection and output three-state control. ADSP is ignored if  $\overline{CE}_1$  is HIGH.

### Single Read Accesses

A single read access is initiated when the following conditions are satisfied at clock rise: (1)  $\overline{CE}_1$ ,  $\overline{CE}_2$ , and  $\overline{CE}_3$  are all asserted active, and (2)  $\overline{ADSP}$  or  $\overline{ADSC}$  is asserted LOW (if the access is initiated by ADSC, the write inputs must be deasserted during this first cycle). The address presented to the address inputs is latched into the address register and the burst counter/control logic and presented to the memory core. If the  $\overline{OE}$  input is asserted LOW, the requested data will be available at the data outputs a maximum to  $t_{CDV}$  after clock rise. ADSP is ignored if  $\overline{CE}_1$  is HIGH.

### Single Write Accesses Initiated by ADSP

This access is initiated when the following conditions are satisfied at clock rise: (1)  $\overline{CE}_1$ ,  $\overline{CE}_2$ ,  $\overline{CE}_3$  are all asserted active, and (2) ADSP is asserted LOW. The addresses presented are loaded into the address register and the burst inputs ( $\overline{GW}$ ,  $\overline{BWE}$ , and  $\overline{BW[A:B]}$ ) are ignored during this first clock cycle. If the write inputs are asserted active (see Write Cycle Descriptions table for appropriate states that indicate a write) on the next clock rise, the appropriate data will be latched and written into the device. Byte writes are allowed. During byte writes,  $BW_A$  controls  $DQ_A$  and  $BW_B$  controls  $DQ_B$ . All I/Os are three-stated during a byte write. Since this is a common I/O device, the asynchronous  $\overline{OE}$  input signal must be deasserted and the I/Os must be three-stated prior to the presentation of data to DQs. As a safety precaution, the data lines are three-stated once a write cycle is detected, regardless of the state of OE.

### Single Write Accesses Initiated by ADSC

This write access is initiated when the following conditions are satisfied at clock rise: (1)  $\overline{CE}_1$ ,  $\overline{CE}_2$ , and  $\overline{CE}_3$  are all asserted

active, (2)  $\overline{ADSC}$  is asserted LOW, (3)  $\overline{ADSP}$  is deasserted HIGH, and (4) the write input signals ( $\overline{GW}$ ,  $\overline{BWE}$ , and  $\overline{BW[A:B]}$ ) indicate a write access. ADSC is ignored if ADSP is active LOW.

The addresses presented are loaded into the address register and the burst counter/control logic and delivered to the memory core. The information presented to  $DQ_{[A:D]}$  will be written into the specified address location. Byte writes are allowed. During byte writes,  $BW_A$  controls  $DQ_A$ ,  $BW_B$  controls  $DQ_B$ . All I/Os are three-stated when a write is detected, even a byte write. Since this is a common I/O device, the asynchronous OE input signal must be deasserted and the I/Os must be three-stated prior to the presentation of data to DQs. As a safety precaution, the data lines are three-stated once a write cycle is detected, regardless of the state of OE.

### Burst Sequences

The CY7C1325F provides an on-chip two-bit wraparound burst counter inside the SRAM. The burst counter is fed by  $A_{[1:0]}$ , and can follow either a linear or interleaved burst order. The burst order is determined by the state of the MODE input. A LOW on MODE will select a linear burst sequence. A HIGH on MODE will select an interleaved burst order. Leaving MODE unconnected will cause the device to default to a interleaved burst sequence.

### Sleep Mode

The ZZ input pin is an asynchronous input. Asserting ZZ places the SRAM in a power conservation "sleep" mode. Two clock cycles are required to enter into or exit from this "sleep" mode. While in this mode, data integrity is guaranteed. Accesses pending when entering the "sleep" mode are not considered valid nor is the completion of the operation guaranteed. The device must be deselected prior to entering the "sleep" mode. CEs, ADSP, and ADSC must remain inactive for the duration of  $t_{ZREC}$  after the ZZ input returns LOW.

**Notes:**

- X = "Don't Care." H = Logic HIGH, L = Logic LOW.
- $\overline{WRITE} = L$  when any one or more Byte Write enable signals ( $\overline{BW}_A$ ,  $\overline{BW}_B$ ) and  $\overline{BWE} = L$  or  $\overline{GW} = L$ .  $\overline{WRITE} = H$  when all Byte write enable signals ( $\overline{BW}_A$ ,  $\overline{BW}_B$ ),  $\overline{BWE}$ ,  $\overline{GW} = H$ .
- The DQ pins are controlled by the current cycle and the  $\overline{OE}$  signal.  $\overline{OE}$  is asynchronous and is not sampled with the clock.
- The SRAM always initiates a read cycle when  $\overline{ADSP}$  is asserted, regardless of the state of  $\overline{GW}$ ,  $\overline{BWE}$ , or  $\overline{BW}_{[A, B]}$ . Writes may occur only on subsequent clocks after the  $\overline{ADSP}$  or with the assertion of  $\overline{ADSC}$ . As a result,  $\overline{OE}$  must be driven HIGH prior to the start of the write cycle to allow the outputs to three-state.  $\overline{OE}$  is a don't care for the remainder of the write cycle.
- $\overline{OE}$  is asynchronous and is not sampled with the clock rise. It is masked internally during write cycles. During a read cycle all data bits are three-state when  $\overline{OE}$  is inactive or when the device is deselected, and all data bits behave as output when  $\overline{OE}$  is active (LOW).

Shaded areas contain advance information.

**Notes:**

7. Overshoot:  $V_{IH}(AC) < V_{DD} + 1.5V$  (Pulse width less than  $t_{CYC}/2$ ), undershoot:  $V_{IL}(AC) > -2V$  (Pulse width less than  $t_{CYC}/2$ ).
8.  $T_{Power-up}$ : Assumes a linear ramp from 0v to  $V_{DD}(\text{min.})$  within 200ms. During this time  $V_{IH} \leq V_{DD}$  and  $V_{DDQ} \leq V_{DD}$ .

**Notes:**

10. This part has a voltage regulator internally; t<sub>POWER</sub> is the time that the power needs to be supplied above V<sub>DD</sub>(minimum) initially before a read or write operation can be initiated.
11. t<sub>CHZ</sub>, t<sub>CLZ</sub>, t<sub>OELZ</sub>, and t<sub>OEHZ</sub> are specified with AC test conditions shown in part (b) of AC Test Loads. Transition is measured ± 200 mV from steady-state voltage.
12. At any given voltage and temperature, t<sub>OEHZ</sub> is less than t<sub>OELZ</sub> and t<sub>CHZ</sub> is less than t<sub>CLZ</sub> to eliminate bus contention between SRAMs when sharing the same data bus. These specifications do not imply a bus contention condition, but reflect parameters guaranteed over worst case user conditions. Device is designed to achieve High-Z prior to Low-Z under the same system conditions.
13. This parameter is sampled and not 100% tested.
14. Timing reference level is 1.5V when V<sub>DDQ</sub> = 3.3V and is 1.25V when V<sub>DDQ</sub> = 2.5V.
15. Test conditions shown in (a) of AC Test Loads unless otherwise noted.

**Timing Diagrams**  
**Read Cycle Timing<sup>[16]</sup>**

**Notes:**

16. On this diagram, when  $\overline{CE}$  is LOW:  $\overline{CE}_1$  is LOW,  $CE_2$  is HIGH and  $\overline{CE}_3$  is LOW. When  $\overline{CE}$  is HIGH:  $\overline{CE}_1$  is HIGH or  $CE_2$  is LOW or  $\overline{CE}_3$  is HIGH.  
 17. Full width write can be initiated by either GW LOW; or by GW HIGH, BWE LOW and  $BW_{[A:B]}$  LOW.

**Read/Write Timing<sup>[16, 18, 19]</sup>**

**Notes:**

18. The data bus (Q) remains in high-Z following a WRITE cycle, unless a new read access is initiated by  $\overline{ADSP}$  or  $\overline{ADSC}$ .

19.  $\overline{GW}$  is HIGH.

**ZZ Mode Timing<sup>[20, 21]</sup>**

**Notes:**

20. Device must be deselected when entering ZZ mode. See Cycle Descriptions table for all possible signal conditions to deselect the device.

21. DQs are in high-Z when exiting ZZ sleep mode.
