DESCRIPTION

The 74HC/HCT652 are high-speed SI-gate CMOS devices and are pin compatible with Low power Schottky TTL (LSTTL). They are specified in

compliance with Jedec standard no. 7A.

The 74HC/HCT652 consist of 8 non-inverting bus transceiver circuits with 3-state outputs, D-type flip-flops and central circuitry arranged for multiplexed transmission of data directly from the data bus or from the internal storage registers. Data on the "A" or "B" or both buses, will be stored in the internal registers, at the appropriate clock pins (CP_{AB} or CP_{BA}) regardless of the select pins (S_{AB} and S_{BA}) or output enable (OE_{AB} and $\overline{OE}_{BA}$) control pins. Depending on the select inputs S_{AB} and S_{BA} data can directly go from input to output (real time mode) or data can be controlled by the clock (storage mode), this is when the output enable pins this operating mode permits. The output enable pins OE_{AB} and $\overline{OE}_{BA}$ determine the operation mode of the transceiver. When OE_{AB} is LOW, no data transmission from A_n to B_n is

possible and when $\overline{OE}_{BA}$ is HIGH, there is no data transmission from B_n to A_n possible. When S_{AB} and S_{BA} are in the real time transfer mode, it is also possible to store data without using the internal D-type flip-flops by simultaneously enabling OE_{AB} and $\overline{OE}_{BA}$. In this configuration each output reinforces its input. Thus when all other data sources to the two sets of bus lines are at high-impedance, each set of the bus lines will remain at its last state. This type differs from the HC/HCT646 in one extra bus-management function. This is the possibility to transfer stored "A" data to the "B" bus and transfer stored "B" data to the "A" bus at the same time. The examples at the application information demonstrate all bus management functions. Schmitt-trigger action in the clock inputs makes the circuit highly tolerant to slower clock rise and fall times.

QUICK REFERENCE DATA

	propagation delay S_{AB}/S_{BA} to B_n/A_n		20	23	ns
t_{PHZ}/t_{PZL}	3-state output enable time $OE_{AB}/\overline{OE}_{BA}$ to B_n/A_n		14	15	ns

C_I	input capacitance		3.5	3.5	pF
C_{PD}	power dissipation capacitance per channel	notes 1 and 2	26	28	pF

Notes

1. C_{PD} is used to determine the dynamic power dissipation (P_D in μW):

$$P_D = C_{PD} \times V_{CC}^2 \times f_i + \sum (C_L \times V_{CC}^2 \times f_o) \text{ where:}$$

f_i = input frequency in MHz; C_L = output load capacitance in pF;

f_o = output frequency in MHz; V_{CC} = supply voltage in V;

$\sum (C_L \times V_{CC}^2 \times f_o)$ = sum of the outputs

2. For HC the condition is $V_I = \text{GND to } V_{CC}$
For HCT the condition is $V_I = \text{GND to } V_{CC} - 1.5 \text{ V}$
